The high school-vocational course should contain topics that could be divided into cultural, technical and vocational subjects. Based on Regents' values the cultural subjects would give 96 1-2 credits, the technical 17 credits and the vocational 32 credits, a total offering of 145 1-2 credits of which 102 1-2 would be required and 43 be optional, somewhat as outlined in a table marked "D" accompanying this communication.

The two years hospital nursing course should require for admission a provisional nurse diploma or certificate from the University of the State of New York. Theory should cover a

## THE ANNUAL MEETING

The arrangements are approaching completion for the Annual Meeting of the Medical Society of the State of New York to be held on May 9-12 in Niagara Falls. The Scientific Committee, headed by Dr Samuel J. Kopetzky of New York, has prepared a balanced program which appears on page 420 of this JOURNAL. The local committee, under the Chairmanship of Dr Frederick J. Schnell of North Tonawanda, has arranged for the accommodation and entertainment of the

physicians, while an associated committee of ladies with Mrs W. H. Hodge as Chairman, will look after the comfort and pleasure of the attending ladies.

Niagara Falls is a compact city, and all the hotels and meeting places are within an area of one block, thus insuring that convenience and sociability that has always been associated with the meetings of the Society when they have been held in one of the smaller cities.

## MEDICAL SOCIETY OFFICE HOLDING

The officers and committeemen of the Medical Society of the State of New York, its district branches, and its component county societies, number over one thousand physicians, or about ten per cent of the membership of the State Society. To hold office in an official medical society is both an honor and a responsibility. The honor is often qualified by the necessity of filling a position for which the highest type of man is not always available. It has been an established custom that office holding shall be by rotation so that every member may have an incentive to aspire to the positions and develop his talents in the specialties of civic medicine and public health.

It is commonplace to say that physicians differ widely in their qualifications for office holding just as they differ in other respects, but it is a mistake to criticize an office holder for his shortcomings when he lacks the genius to fill the position according to the very highest standards. It cannot be expected that one out of every ten physicians shall be a genius in administrative medicine.

Shall medical office holding be discontinued and societies lapse in their activities because of the lack of leaders of the highest standards? Surgeons, and neurologists, and other specialists are extremely tolerant of family doctors who are confronted with special problems beyond the standard of their ability and attainment. Intolerance is found among public health officials and the workers in lay organizations, for their standards are set at the top by leaders in research laboratories and medical schools, while standards of the private practice of medicine are largely those which the average doctor can put to practice.

A county medical society deals with the average doctor treating a person of average intelligence. Its membership is made up of doctors who must earn their living by pleasing their patients. The members have no time to experiment with new theories or undertake new methods of reaching the people. Yet they are keen judges of what is workable, and are anxious to undertake new activities which will be appreciated by their fellow practitioners and the public. It is therefore desirable that average men from the ranks of the profession should fill the offices and committees of a county medical society. It is far better that the average members should run the society than that it should be dominated by im-

practical theorists whom the members will not follow.

However, let no one make the mistake of thinking that men of genius and high standing in public health and civic medicine have only a minor place in the county society. They are the powers that make the society go, and whether they hold office or not, they supply the force which is behind the activities of the society. Fortunate is that society which has a few leaders in public health and civic medicine who quietly act as consultants and advisors to the officers in their endeavors to reach both their professional brethren and the public.

Office holding in a county medical society is an opportunity for acquiring knowledge and self development. It is a laboratory of experience in methods of dealing with people. A member misses one of the great benefits of his medical society if he does not accept an office or a committee assignment and assume the responsibility for some of the activities of the society. There is a joy and satisfaction in doing something useful to others.

An office holder in a county medical society is not to be judged entirely by his tangible accomplishments during his term. He is successful if he retires from office with an increased interest in his civic duties. The ideal condition is that an average member shall take his turn in filling an office or committee, shall use the office for his own education, and shall return to the ranks with an increased interest in the activities of his society.

The present great movement in county societies is that of reaching well people in medical lines. People who are sick demand the attention of the doctor, but skillful salesmanship is needed to sell medical services to a well individual or a community, or even to give it away. Medical practice among the well is now in the stage of demonstration in which the medical profession is expected to give away samples of its wares to the well with the expectation of creating a future demand for such services. The practice of preventive medicine at present is not remunerative to the average practitioner of medicine, and yet the family doctor is conscientious in his wish to serve his family and community along all lines of modern medicine. His present opportunity to discharge the civic duty which stares him in the face, is to work through his county medical society and accept his share of office holding and of service on its committees.

## THE A M A CONFERENCE ON PUBLIC HEALTH

The relation of physicians to public health was the principal topic of discussion at a conference called by the American Medical Association on March 24 and 25 in Chicago, an account of which appears on page 428 of this JOURNAL. This was the first conference to be called to consider the topic, and its program was largely tentative, and was designed for the diagnosis rather than the treatment of present conditions. A list of those in attendance was published in the *Journal of the American Medical Association* of April 2, and showed a great preponderance of professional public health workers connected with both official and lay organizations.

The Medical Society of the State of New York was almost the only society of general practitioners of medicine that was prominently represented at the conference, and its President, Dr. George M. Fisher, gave the only concrete suggestion that was made. He introduced a resolution that was carried, that the conference suggest to the Trustees of the American Medical Association the appointment of a committee on Public Relations to work nationally along the lines of a similar committee that is functioning in New York State.

The Conference has great possibilities, and it is hoped that similar ones will be held annually.

## THE VERNAL EQUINOX

The New York *Herald-Tribune*, of March 21, has an editorial reference to the vernal equinox,—that critical milestone when the sun crosses the equator on its return journey northward. This event was momentous to the ancients, and the priests performed elaborate ceremonies and did costly sacrifices in order to persuade the life-giving sun to step across the mystical line and so ensure its return to bless the earth with a fruitful summer. And great was the renown and reward of the priests who could control the movements of the mighty sun and dispense light and life at their whim.

Men change the premises of their arguments

in accordance with scientific discoveries, but the wheels of the brain are exactly the same that they were a thousand years ago, and the grist of conclusions which they turn out are influenced less by the facts that are poured into the mental hopper, than by the processes to which they are subjected.

Some one sets up an imitation temple of healing labelled "Spinal adjustments." The curious wayfarers flock to it, and the white-gowned attendants say, "Behold the healthy throng who leave our portals. The sun of healing rises and sets at our command."

Every day is a vernal equinox for the quacks.

## THE EDITORIAL WASTE BASKET

The waste basket is the most overworked piece of furniture in every editorial office. The amount of ready-made copy sent to the humblest of editors is appalling. Mimeographed copies cost little, and if one in a thousand is used, the price of the advertisement is small.

The medical editor does not have to be highly skilled and learned in order to see through most of the schemes which are proposed to him. This JOURNAL recently received from a "News Service" a beautiful photograph of a young Berlin "Professor" who "created a sensation" by "removing

the organs of a pregnant woman and so nurturing the child that it was born normal. The ordinary processes continued after the organ had been removed and Dr. X was able to make a motion picture of the development of the child."

There are some who would criticize the editor for refusing even to investigate that news report. An editor of a tabloid morning daily might possibly be interested in a few singles taken from the movie, but even he would find no thrill in the placid countenance of the advertising gynecologist.

## SCARLET FEVER

Scarlet fever is unusually prevalent throughout New York State. Every community in which it appears minimizes its danger and points to the mildness of most of the cases as evidence that the disease has lost its former virulence. The fact is that the comparative absence of serious complications is due largely to the intelligent care given to the cases by physicians. Neglect the care of the individual sick child, and

scarlet fever would doubtless be as crippling and deadly as ever.

The prevalence of mild cases of scarlet fever is now leading to disputes over diagnoses and the isolation of cases. It was expected that the Dick test and other recent discoveries in the bacteriology of scarlet fever would enable physicians to diagnose the disease as readily and accurately as they now determine the existence of diphtheria.

That expectation has not been realized, and physicians and health officers must still make their diagnoses principally on the clinical symptoms and signs

The relation of septic sore throat and scarlet fever has yet to be fully elucidated. Clinical observers have noted the occurrence of cases of both sore throat and scarlet fever among the children in families. While all the children of a family, for example, will have sore throat and fever, half of them will have a typical scarlet fever eruption, and the rest will have no visible eruption at all. The question arises, were all the cases scarlet fever?

In one milk-borne outbreak of eighty cases of septic sore throat that were studied intensively fifty patients had scarlet fever eruptions, and only thirty-seven of them showed desquamation. Did all these patients have scarlet fever?

Some of these newer problems will be discussed at the 14th Annual Meeting of the American Association of Immunologists to be held on April 14 and 15 in the new medical school at Rochester, N. Y. An account of the proceedings will appear in an early issue of the *Journal of Immunology*, and will be of interest to every doctor.

## LOOKING BACKWARD

### THIS JOURNAL TWENTY YEARS AGO

*Milk Control in New York City* This Journal for April, 1907, records that a hearing was held by the Board of Aldermen on March 7 on the proposal to pasteurize all the milk sold in New York City, unless it came from cows free from tuberculosis, and contained no more than 50,000 bacteria per cubic centimeter. Pasteurization was to consist of holding the milk at a temperature of 167° F. for at least thirty minutes. Regarding the proposal the Journal says:

"The Health Department feels that its most important work is to supervise the conditions under which milk is produced, preserved, transported and sold. The Department of Health has under consideration further measures, but does not think it advisable at present to adopt partial or untried measures. The feeling is that the general pasteurization of the City's milk is too complex an undertaking and that it might lead to neglect in the more important things."

The New York Academy of Medicine took action on the milk problem on March 21 by passing the following resolution:

"(1) That the Section on Public Health of the New York Academy of Medicine does not believe in the necessity of the compulsory pasteurization of all of the milk supply of New York City, but recommends for the present to all those

whose milk supply cannot be proven to be thoroughly inspected and wholesome, and mainly the milk destined for the feeding of infants unless it is "certified," to boil their milk when delivered in the morning for three minutes.

"(2) That the health of the City of New York demands a persistence in the policy of supervision of farms, dairies, and creameries, supervision at the points of distribution in the City to the consumer, whether the milk that is distributed has been pasteurized or not.

"(3) That local and State health authorities and the Bureau of Animal Industry of the United States Department of Agriculture should co-operate with milk producers to prevent the occurrence of communicable diseases in cattle and their caretakers."

Those who attended the lectures of Professor Charles Chandler in the College of Physicians and Surgeons fifteen years previous to the date of the above quotation, will recall his thrilling descriptions, controversies and debates with other eminent authorities who were bitterly opposed to his suggestions for the establishment of standards for milk, and for the public control of milk supplies. Professor Chandler won in nearly every particular within a decade, but milk still figures large in public health and politics.

# MEDICAL PROGRESS

**The Chemical Constitution of Insulin**—Casimir Funk, discoverer of vitamins, announces in a brief preliminary communication in the *Deutsche medizinische Wochenschrift*, January 1, 1927, that insulin consists of and has been decomposed into three crystallizable substances which differ throughout from the parent body. He describes two of these as follows: one body to be known provisionally as A, does not exert a uniform action on animals. In 70 to 80 per cent of normal rabbits tested, an injection of the A substance reduced the blood sugar anywhere from 10 to 50 per cent. The higher the percentage of sugar in the blood the greater the reduction. The same substance is thought to produce this reduction when given per os, but this requires further experimental support. Funk with Landberg has tested the A substance on human diabetics and non-diabetics, but the authors do not care to go on record as yet as to the outcome of these tests although thus far the results agree with those obtained with rabbits. The second substance isolated, to be known for the time being as B, may be regarded as a hormone with very complex action. Given to normal rabbits per os or by parenteral injection the result is a marked increase in the percentage of blood sugar, up to 800 per cent when given as long as six days. It is highly toxic and causes death in about 10 days, the animals presenting anemia and edema. This substance probably plays a role in the genesis of alimentary glycosuria and diabetes.

**Treatment of Ulcers by Insulin**—D. Adlersberg and A. Perutz have studied the regenerative efforts of the skin as modified by the local application of insulin. After preliminary experiments with artificial ulcers induced on animals, the first essays on man were in cases of torpid varicose ulcers. In a woman of 61 with large ulcers of 15 years standing, who had gone from ambulatorium to clinic and back again, the results obtained were astonishing. After 3 or 4 daily instillations of insulin solution on these lesions a tendency to heal was already in evidence and soon the whole ulcer area was strewn with islets of granulation. The ulcers changed from dry to secreting and in 10 days epithelization was complete. A similar result was next obtained in an ulcer caused by a burn, and in all the authors have cured 10 cases of these torpid ulcers of long standing by this simple resource. In the mean time two similar cases had refused to respond save imperfectly. Even here there had been a decided and partly successful attempt to heal, but some unknown factor interfered. One patient had pul-

monary tuberculosis and an anal fistula while the other lesions were of a fungoid character. The authors are not, strictly speaking, pioneers in this province, for several others had noticed that in insulin cures of diabetes chronic ulcers had unexpectedly healed. They are continuing their interesting investigations into other forms of ulceration.—*Klinsche Wochenschrift*, January 15, 1927.

**Action of Insulin in Hepatic Disease**—O. Klein and H. Holzer call attention to the fact that the new drug possesses some sort of power over jaundice as a symptom, especially if the patient at the same time receives large amounts of carbohydrate foods. It appears to make no difference how long the jaundice has existed. At Professor Klein's Prague clinic 26 cases of hepatic disease have now been treated in this manner. In 11 cases of catarrhal jaundice the latter symptom promptly disappeared, although they were mostly severe cases of long standing. Even in 5 cases of cancer, although the disease was not otherwise favorably influenced, the jaundice either vanished outright or improved notably and the same is true of chronic hepatitis and cirrhosis. The doses given were very large—80 to 100 units daily. It is known that in hepatic disease the alkaline-base ratio is often disturbed and that in the severest forms there is a marked acidosis (phosphorus poisoning, acute yellow atrophy, etc.). Eight patients were studied from this angle and in four of these an increase in the alkali reserve was recognized by the Van Slyke method. To sum up, insulin seems to affect favorably the carbohydrate metabolism, blood sugar regulation, bilirubin metabolism, acid-base equilibrium, water economy, etc., in these patients, and in hepatic subjects all of these are impaired. Richter and Umber have arrived independently at the same conclusions. The best carbohydrate to feed the patient is dextrose, which, even when given alone, has a favorable action in promoting efficiency of liver function in disease of this organ.—*Klinsche Wochenschrift*, January 22, 1927.

**Dangers of Insulin Hypoglycemia in Children**—R. Priesel and R. Wagner of von Pirquet's pediatric clinic in Vienna refer to a death from insulin reported from Breslau in a recent number of the *Wochenschrift*. The patient was a girl of 8 years, found to be very sensitive to insulin when the latter was administered for her diabetes. Small doses were sufficient to bring down the blood sugar notably, but the high percentage promptly reappeared so that the girl os-

cillated between hypoglycemia and acidosis. It was suggested by the Breslau clinicians that the hypoglycemic reaction be strictly avoided in all cases of child diabetes. Since the insulin treatment must be maintained over long months it is not well to intern the child in a hospital but it should be treated at home although there are times when a short hospital sojourn is quite appropriate. In analyzing this death it is apparent that the evidences of severe hypoglycemia were present in the staring look, sweating, and twitchings about the mouth, which symptoms yielded somewhat to ten grams of glucose given by the mouth. Later appeared coma and convulsions which did not yield to intravenous glucose. The Vienna authors appear to believe that the child might have been benefited by much larger amounts of glucose given relatively early. When the Breslau men resorted to larger doses it was probably too late to influence favorably the hypoglycemia. In the von Pirquet clinic insulin has been used for several years in child diabetes and much had to be learned at a high cost before a safe plan could be evolved—for example in regard to the avoidance of the hypoglycemic reaction. Children must be treated at home and the parents instructed to give carbohydrates by the mouth after each insulin injection to avert the hypoglycemic syndrome.—*Klumsche Wochenschrift*, January 8, 1927

**Increasing Weight with Insulin**—Professor E. Frank speaks of the astonishment with which one sees the emaciated, cachectic subject with diabetes transformed into an individual with the bloom of health as the signs of senescence give way to a veritable rejuvenescence. Naturally insulin was soon tested on nondiabetics with the same evidences of cachexia—first in primary constitutional emaciation and cases not due to severe organic disease, and sometimes with remarkable gain in weight. The fattening type of diet with 20 to 40 daily units of insulin constitutes the treatment, the drug of course being given by injection only. In this type of cure where no insufficiency of the pancreas is apparent there must be some specific mechanism involved and this probably includes the power of insulin to cause the water content of the tissues to be retained. In more pathological types of emaciation findings of reporters differ. The first thought in this connection is the value of insulin in tuberculosis. In the patient with high fever there is no reason to believe that the consumptive will benefit from it, but in the chronic afebrile, or slightly febrile patient, it might be well worth testing, although it is possible that the foreign protein in the injection would determine a focal reaction—perhaps an hemoptysis. In cancerous cachexia there is little reason to anticipate any benefit, but the thy-

reotoxicoses seem well adapted to insulin and good results have been reported—*Deutsche medizinische Wochenschrift*, February 4, 1927

**The Treatment of Typhoid and Paratyphoid Fevers with Staphylococcic Vaccines**—Valdemar Bie (*Acta Medica Scandinavica*, Dec. 10, 1926, lxx, 1-2) agrees with those who hold that the vaccine treatment of typhoid and paratyphoid fevers is not specific, but corresponds to other forms of nonspecific protein therapy. For four years he has been employing vaccine treatment for these diseases, during the first two years of this period he used typhoid vaccines, but for the past two years he employed exclusively staphylococcic vaccines which gave results equally as satisfactory as did the specific vaccines. The staphylococcic vaccines are preferable because the treatment can be begun on the basis of the clinical diagnosis alone without reference to the Widal reaction. Since the intravenous injection of adequate quantities of bacillary proteins gives rise to chills and a critical fall of temperature, often accompanied by a dangerous collapse, Bie tried intramuscular injections, which produce a temperature reaction of only several tenths of a degree, Centigrade, and following which collapse has never been observed. The local reaction at the site of the injection is insignificant. The staphylococcus vaccine contains 1000 million bacilli (killed with carbolic acid) to the cubic centimeter. The intramuscular injections are given on five consecutive days, beginning with a small dose of 100 million, and continuing on successive days with 200, 400, 700, and on the fifth day 1000 million bacilli. The dosage for children is the same as that for adults. It is important to start the treatment with a small dose, the temperature often begins to fall after the injection of 0.1 c.c. (100 million). Usually defervescence occurred about the eighth day after commencing the treatment and ushered in the convalescent stage, thus showing that the staphylococcic vaccines are curative as well as antipyretic. In 39 of a series of 51 cases of paratyphoid fever, the temperature began to fall during or immediately after the treatment, in 4 cases the result was doubtful, defervescence taking place slowly, while in 8 cases the treatment was ineffective. In 35 of a series of 54 cases of typhoid fever the results were good, in 3 cases doubtful, while in 9 cases the vaccines were ineffective. In this series there were 7 deaths. Bie concludes that the use of staphylococcic vaccines reduces the mortality and shortens the course of typhoid and paratyphoid fevers.

**Chills in Acute Appendicitis**—Ralph Colp presents an analysis of 2,841 cases of acute appendicitis treated in Mt. Sinai Hospital, New York City, with reference to the significance of chills, concerning which decidedly contradictory

# MEDICAL PROGRESS

**The Chemical Constitution of Insulin**—Casimir Funk, discoverer of vitamins, announces in a brief preliminary communication in the *Deutsche medizinische Wochenschrift*, January 1, 1927, that insulin consists of and has been decomposed into three crystallizable substances which differ throughout from the parent body. He describes two of these as follows: one body to be known provisionally as A, does not exert a uniform action on animals. In 70 to 80 per cent of normal rabbits tested, an injection of the A substance reduced the blood sugar anywhere from 10 to 50 per cent. The higher the percentage of sugar in the blood the greater the reduction. The same substance is thought to produce this reduction when given per os, but this requires further experimental support. Funk with Landberg has tested the A substance on human diabetics and non-diabetics, but the authors do not care to go on record as yet as to the outcome of these tests although thus far the results agree with those obtained with rabbits. The second substance isolated, to be known for the time being as B, may be regarded as a hormone with very complex action. Given to normal rabbits per os or by parenteral injection the result is a marked increase in the percentage of blood sugar, up to 800 per cent when given as long as six days. It is highly toxic and causes death in about 10 days, the animals presenting anemia and edema. This substance probably plays a role in the genesis of alimentary glycosuria and diabetes.

**Treatment of Ulcers by Insulin**—D. Adlersberg and A. Perutz have studied the regenerative efforts of the skin as modified by the local application of insulin. After preliminary experiments with artificial ulcers induced on animals, the first essays on man were in cases of torpid varicose ulcers. In a woman of 61 with large ulcers of 15 years standing, who had gone from ambulatorium to clinic and back again, the results obtained were astonishing. After 3 or 4 daily instillations of insulin solution on these lesions a tendency to heal was already in evidence and soon the whole ulcer area was strewn with islets of granulation. The ulcers changed from dry to secreting and in 10 days epithelization was complete. A similar result was next obtained in an ulcer caused by a burn, and in all the authors have cured 10 cases of these torpid ulcers of long standing by this simple resource. In the mean time two similar cases had refused to respond save imperfectly. Even here there had been a decided and partly successful attempt to heal, but some unknown factor interfered. One patient had pul-

monary tuberculosis and an anal fistula while the other lesions were of a fungoid character. The authors are not, strictly speaking, pioneers in this province, for several others had noticed that in insulin cures of diabetes chronic ulcers had unexpectedly healed. They are continuing their interesting investigations into other forms of ulceration.—*Klinische Wochenschrift*, January 15, 1927.

**Action of Insulin in Hepatic Disease**—O. Klein and H. Holzer call attention to the fact that the new drug possesses some sort of power over jaundice as a symptom, especially if the patient at the same time receives large amounts of carbohydrate foods. It appears to make no difference how long the jaundice has existed. At Professor Klein's Prague clinic 26 cases of hepatic disease have now been treated in this manner. In 11 cases of catarrhal jaundice the latter symptom promptly disappeared, although they were mostly severe cases of long standing. Even in 5 cases of cancer, although the disease was not otherwise favorably influenced, the jaundice either vanished outright or improved notably and the same is true of chronic hepatitis and cirrhosis. The doses given were very large—80 to 100 units daily. It is known that in hepatic disease the alkaline-base ratio is often disturbed and that in the severest forms there is a marked acidosis (phosphorus poisoning, acute yellow atrophy, etc.). Eight patients were studied from this angle and in four of these an increase in the alkali reserve was recognized by the Van Slyke method. To sum up, insulin seems to affect favorably the carbohydrate metabolism, blood sugar regulation, bilirubin metabolism, acid-base equilibrium, water economy, etc., in these patients, and in hepatic subjects all of these are impaired. Richter and Umber have arrived independently at the same conclusions. The best carbohydrate to feed the patient is dextrose, which, even when given alone, has a favorable action in promoting efficiency of liver function in disease of this organ.—*Klinische Wochenschrift*, January 22, 1927.

**Dangers of Insulin Hypoglycemia in Children**—R. Priesel and R. Wagner of von Pirquet's pediatric clinic in Vienna refer to a death from insulin reported from Breslau in a recent number of the *Wochenschrift*. The patient was a girl of 8 years, found to be very sensitive to insulin when the latter was administered for her diabetes. Small doses were sufficient to bring down the blood sugar notably, but the high percentage promptly reappeared so that the girl os-

of these measures the patient finally showed a negative seroreaction in the blood and spinal fluid. A strain of these spirochetes which may have been weakened somewhat by the preceding treatment (taken after the sodium salvarsan treatment) was introduced under the scrotal skin of 3 rabbits. Inoculation chancres developed promptly and the spirochetes obtained from them showed the same vigorous activity. However the rabbit syphilis yielded very readily to the usual treatment, which fact seemed to show that it was not the virulence of the spirochete so much as the lowered resistance of the patient which required study. The authors on this evidence totally reject the theory of special virulent strains of this organism to account for peculiarities in the course of syphilis in man. The combination of bismuth and salvarsan has in general given the authors the best results. Thus the disease has been freed from the contagious relapses which do so much to keep it active in the community, the case detailed being a notable exception. They also trust this plan of treatment properly spaced to clean the spinal fluid and antagonize the later development of neuro- and metasyphilis.—*Deutsche medizinische Wochenschrift*, January 7, 1927

**Besredka's Local Immunity in Cataract Operations**—R. Comenge suggests immunization of cataract patients before operation after Besredka's method of local vaccination. At the present time in ophthalmology an autovaccine is prepared from the bacteria found in the tears of patients with infection of the conjunctival sac, and this is injected beneath the integument, although apparently not in connection with surgical intervention. In the case of the Besredka method the antiviral might be instilled into the conjunctival sac one day before a cataract operation. The vaccine itself is entirely nonirritating and can be obtained as a specific against any kind of pathogenic micro-organism. If more than one such is found in the conjunctiva a mixed vaccine should be employed. The chief danger in cataract operation is a panophthalmitis, in which the patient, instead of recovering his vision, loses his eye, and the author urges local immunization to prevent this catastrophe.—*El Siglo Médico*, January 15, 1927

**Failure of Tetanus Antitoxin in Animal Experiment**—Professor A. Wolff-Eisner refers to the unknown factor in serotherapy which sometimes asserts itself, especially in connection with tetanus. This may explain why tetanus antitoxin has failed in man as a curative measure, however valuable it may be as a prophylactic. In testing small laboratory animals it has been the custom to give a control injection of serum free from antitoxin, and it is commonly believed that in these animals injections containing antitoxin are

very virulent. The author, however, in making some tests on mice and guinea pigs found that a highly potent serum was no longer active. Since evidently there was no question of defective preparations or technique it is evident that some unknown law is involved through which tetanus antitoxin does not act absolutely. This unknown factor cannot be in the preparations but must lie in the tissues of the test animals. Thus different species of the same kind of animal show differences in their behavior with tetanus antitoxin. The animal which behaves in a refractory or negative manner toward the antitoxin will also be found to show peculiarities in fixation of the toxin of tetanus. The power of fixation of the toxin is feeble and the response to the antitoxin is negative. The superstructure of twenty years which has been built up around laboratory experiments and standardizing tests on such small creatures as mice, frogs, fowls, rabbits, etc., may prove to be only a cobweb unless we can determine the conditions which permit these negative results. We must also extend the study to the larger animals.—*Deutsche medizinische Wochenschrift*, January 14, 1927

**The Treatment of Tetanus**—Samuel Oscar Freedlander (*Annals of Surgery*, March, 1927, lxxv, 3) records a series of 25 consecutive cases of tetanus treated uniformly and analyzed in order to determine a basis for conclusions as to the therapeutic value of tetanus antitoxin. The local treatment consisted in making all parts of the wound accessible to the air by the removal of devitalized tissue. A small amount of antitoxin was usually injected around the wound. Within the first twenty-four hours a total of 50,000 to 150,000 units of antitoxin was given intravenously in two or three injections. This was continued well into convalescence, sometimes as long as twelve to fifteen days, depending upon the muscular rigidity. Morphine was given hypodermically every six hours and chloroform every six hours by rectum. Food and fluids were urged. The aim of the treatment should be to maintain a high concentration of antitoxin in the blood in order to neutralize the toxin already there and also that given off from the focus of infection. The gross mortality rate in this series was 36 per cent. If six cases which terminated fatally before sufficient antitoxin could be administered are excluded, the mortality rate would be 12 per cent. The relatively low mortality rate in this series strengthens the impression that tetanus antitoxin given in large doses intravenously has some therapeutic value. From the observations made on the later cases in this series it seems doubtful whether it is necessary to continue the antitoxin longer than six or seven days.

opinions are held. In this series 192 patients gave a history of having had a real shaking chill and 206 complained of chilly sensations, *i. e.*, in about 68 per cent of the entire series chill was a clinical symptom before operation. The figures indicate that the degree and extent of the gross pathology bear little relation to the occurrence of chills within the first forty-eight hours, so that, as a rule, this symptom is not an index of the severity of the disease. Seventy per cent of all rigors occurred within the first twenty-four hours. A primary chill on the third day, or even later in the course of the disease, seemed to be associated with abscess formation, and the delayed occurrence occasionally heralded the onset of a general peritonitis. The mortality of patients with a single chill was no higher than that for all cases without chill. When a chill is present, especially in gangrenous appendicitis, the possibility of pylephlebitis should be constantly borne in mind and the appendicular mesentery should be carefully investigated for evidence of suppurative pylephlebitis. When chills are multiple a routine ligation or resection of the ileocolic vein should be done, preferably before the actual appendectomy. Postoperative chills are invariably due to suppurative pylephlebitis.—*Annals of Surgery*, February, 1927, vol lxxxv, No 2

**Parasitic Appendicitis**—C. P. Caplesco of Bucharest has devoted many years to the study of the so-called parasitic appendicitis. By parasite he refers to such demizens of the intestine as the ascaris, oxyuris, and trichocephalus. According to Professor Guiard there were on record up to 1910 no less than 200 cases of appendicitis due to these three parasites. Since that year many more have been reported. Other figures in abundance show the great frequency of infestation by these worms in certain groups of men. There are also numerous figures which show the coexistence of parasitism and appendicitis although without establishing any causal relationship. Since 1913 the author has operated on 1,556 cases of appendicitis and of this total he regards 105 cases as of possible parasitic origin, or about 7 per cent. The author is himself a parasitologist and is able to make his own laboratory studies. In his 105 cases he found the oxyuris in the appendix in 94. He concedes, however, that the relation of cause and effect is not straightway apparent. It may be that the parasite enters an appendix already doomed to infection. Moreover, histological studies originally begun by the late Professor Babes and continued by the author, fail to show that the parasite is able to cause a special type of lesion in the appendix. Nor has the author ever found the ova of the parasites in the appendix. The symptomatology is the same, contrary to what is sometimes taught. Finally appendicitis is rare in countries where the worms

most abound.—*Bulletin de l'Académie de Médecine*, Jan 4, 1927

**Alkalinity, Acidity, and Pain**—W. v. Gaza and B. Brandi have already published one article on this subject in which they pointed out a connection between the hydrogen ion concentration and the pain of inflammation. The latter seems to be attended by a local acidosis, and the injection of alkalies locally by neutralizing this acidosis may be the means of alleviating the pain. They made experiments not only with processes like furuncles and phlegmons where there is great local tension, but also with other painful conditions, some of which are noninflammatory. These tests showed that it was possible in an entire series of infectious-inflammatory affections to remove the pain completely and permanently by the injection of certain alkaline solutions. Other relief measures are not contraindicated, for example a tension abscess is punctured and evacuated. To quote a case in point, a journeyman mechanic entered the clinic with a furuncular abscess of the buttocks which infiltrated the entire seat of the affected side. The affection was not only painful in itself but doubly so on the attempt to sit down. The patient asked for an incision but instead an attempt at relief by puncture gave exit to but little pus which contained the staphylococcus. A solution of phosphates of 9.1 hydrogen ion concentration was now injected and in a few moments the patient was rejoiced to note that he was not only free from pain but could seat himself dead weight with the same freedom from suffering. There was no return of the pain and the abscess healed, leaving a sinus. The solution was composed of secondary sodium phosphate with compensatory addition of sodium chloride. To make the solution, take one liter of water add 6 grams (6.49 to be exact) of secondary sodium phosphate and 6 grams (6.44) of common salt. This mixture gives the desired concentration. On the other hand, if injections of solutions which give an acid reaction are injected the pain is increased. If a merely alkaline solution is injected without regard to concentration the action is much slower.—*Klinsche Wochenschrift*, January 1, 1927

**Salvarsan Resistant Spirochetes**—E. Hoffmann and G. Aemuzzi relate the case of a patient who, after his quite recent secondary syphilis had been treated with bismuth and neosalvarsan, developed an outbreak of moist papules of the genitals and throat. The spirochetes found in these lesions seemed unusually active and resisted a new course of sodium salvarsan and a mercurial inunction cure. In fact these organisms did not yield until after a further intensive bismuth-salvarsan treatment, in which neosalvarsan was used in very large doses, and which was followed by a Zittmann sweating cure. After all

whom such physician, dentist, or veterinary surgeon shall personally attend, and such record shall be kept for a period of two years from the date of dispensing or distributing such drugs, subject to inspection, as provided in this Act "

Section 8 of the Act declares

"That it shall be unlawful for any person not registered under the provision of this Act, and who has not paid the special tax provided for by this Act, to have in his possession or under his control any of the aforesaid drugs, and such possession or control shall be presumptive evidence of a violation of this section, and also of a violation of the provisions of Section 1 of this Act. Provided, That this section shall not apply to any employee of a registered person, or to a nurse under the supervision of a physician, dentist or veterinary surgeon registered under this Act, having such possession or control by virtue of his employment or occupation and not on his own account, *or to the possession of any of the aforesaid drugs which has or have been prescribed in good faith by a physician, dentist, or veterinary surgeon registered under this Act*"

Section 1 of this Act was amended on February 24, 1919, so as to contain the following provision

"It shall be unlawful for any person to purchase, sell, dispense, or distribute any of the aforesaid drugs except in the original stamped package or from the original stamped package, and the absence of appropriate taxpaid stamps from any of the aforesaid drugs shall be prima facie evidence of a violation of this section by the person in whose possession same may be found, and the possession of any original stamped package containing any of the aforesaid drugs by any person who has not registered and paid special taxes as required by this section shall be prima facie evidence of liability to such special tax. Provided, That the provisions of this paragraph shall not apply \* \* \* to the dispensing or administration, or giving away of any of the aforesaid drugs to a patient *by a registered physician, dentist, veterinary surgeon, or other practitioner in the course of his professional practice, and where said drugs are dispensed or administered to the patient for legitimate medical purposes*, and the record kept as required by this Act of the drugs so dispensed, administered, distributed, or given away"

Section 1 of the Act provides further that the Commissioner of Internal Revenue, with the ap-

proval of the Secretary of the Treasury, shall make all needful rules and regulations for carrying the provisions of this Act into effect. In supposed furtherance of this power the Internal Revenue Department issued regulations (No 35) which, among other things, provide

"Art 117—A prescription, in order to be effective in legalizing the possession of unstamped narcotic drugs and eliminating the necessity for use of order forms, must be issued for legitimate medical purposes. An order purporting to be a prescription issued to an *addict* or habitual user of narcotics, not in the course of professional treatment in an attempted cure of the habit, but for the purpose of providing the user with narcotics sufficient to keep him comfortable by maintaining his customary use *is not a prescription within the meaning and intent of the Act*, and the persons filling and receiving drugs under such an order, as well as the person issuing it, will be regard as guilty of violation of the law"

"Art 126—Practitioners are permitted to dispense narcotic drugs to bona fide patients pursuant to the legitimate practice of their professions without prescriptions or order forms \* \* \*. However, a record of drugs so dispensed must be kept except when the practitioner is in personal attendance upon the patient. A practitioner is not regarded as in personal attendance upon a patient within the intent of the statute unless he is in personal attendance upon such patient away from his office"

It should be noted that the statute itself makes no reference to "addicts", this word is found in the regulations only. These regulations are valid only if in conformity with the statute. The statute, in the language of the Supreme Court, "says nothing of 'addicts' and does not undertake to prescribe methods for their medical treatment. They are diseased and proper subjects for such treatment, and we cannot possibly conclude that a physician acted improperly or unwisely or for other than medical purposes solely because he has dispensed to one of them, in the ordinary course and in good faith, four small tablets of morphine or cocaine for relief of conditions incident to addiction"

The question before the court was whether the dispensing by the indicted physician of four small tablets of morphine or cocaine was a violation of the Harrison Narcotic Act. The court squarely held that it was not. A sharp distinction, however, was drawn between a case where a doctor administers a narcotic in good faith in pursuance of a bona fide medical practice or where the same is dispensed under the mere pretense that it is in furtherance of such practice,

# LEGAL

By **LLOYD PAUL STRYKER, Esq**  
Counsel, Medical Society of the State of New York.

## THE POWER OF THE FEDERAL GOVERNMENT TO REGULATE THE PRACTICE OF MEDICINE

In our editorial of January first entitled "The Supreme Court of the United States Limits the Practice of Medicine," we discussed at length the opinion of that court in the case of *Lambert v Yellowley*. We expressed there strong approval of the minority opinion and disapprobation of the opinion of the court. There, as will be recalled, it was held that Congress could limit a physician in prescribing more than a fixed amount of vinous or spirituous liquors for his patient. The decision of the court, of course, was based upon the Eighteenth Amendment to the Constitution which in itself marks a radical departure from the accepted functions of the Federal Government. Fortunately, however, the decision in the *Lambert* case is at least limited to a prescription of beverages prohibited by the Eighteenth Amendment. The decision does not otherwise limit or constitute an authority for a restriction upon the practice of medicine.

In rendering an opinion not long ago to your Executive Committee concerning the Harrison Narcotic Act, it was refreshing to reread the case of *Linder vs The United States*, decided by the Supreme Court in October, 1924. In that case Charles O Linder, a duly licensed physician of the state of Washington was indicted by the Federal grand jury in the Eastern district of his state for an alleged violation of Section 2 of the Harrison Narcotic Act. The indictment charged that he had knowingly and unlawfully sold to one Ida Casey one tablet of morphine and a compound, manufacture and derivative of coca leaves and that he had done this not in pursuance of any written order of Ida Casey on a form issued for that purpose by the Commission of Internal Revenue of the United States. The indictment further charged that Ida Casey was a person addicted to the habitual use of morphine and cocaine and known by the defendant to be so addicted. Further, it was alleged that the patient "did not require the administration of either morphine or cocaine by reason of any disease other than such addiction." It was charged also that none of the drugs dispensed were administered or intended to be administered by the doctor to his patient or by any nurse or other person acting under the instructions of the doctor, and that all of the drugs were to be in the possession of the patient with the intention on the part of the doctor that the patient would use the same by self-administration in divided

doses over a period of time, and that the amount of each of the drugs dispensed was "more than sufficient or necessary to satisfy the cravings of Ida Casey therefor if consumed by her all at one time."

In the trial court the defendant was convicted. His conviction was affirmed by the Circuit Court of Appeals, from which court by a writ of certiorari appeal was taken to the United States Supreme Court. By an unanimous decision the conviction of the lower court was reversed. The opinion—a masterly one—in which all of the judges concurred, was written by Mr Justice James McReynolds.

In this era of expansion of Federal power, when the long arm of Washington, through the medium of the Eighteenth Amendment, the income tax amendment and the instrumentalities of countless scores of bureaus and Federal officials reaches out into the states to control the private citizen in so many of his activities, it is indeed refreshing to read the opinion in the *Linder* case, taking from it a renewed confidence that there are some rights of the ordinary citizen which are beyond the supervision and control of Federal power.

The Harrison Narcotic Act became a Federal law on December 17, 1914. Section 2 provides

"That it shall be unlawful for any person to sell, barter, exchange, or give away any of the aforesaid drugs except in pursuance of a written order of the person to whom such article is sold, bartered, exchanged, or given, on a form to be issued in blank for that purpose by the Commissioner of Internal Revenue."

That section further provides

"Nothing contained in this section shall apply \* \* \* To the dispensing or distribution of any of the aforesaid drugs to a patient by a physician, dentist, or veterinary surgeon registered under this Act in the course of his professional practice only. Provided, That such physician, dentist, or veterinary surgeon shall keep a record of all such drugs dispensed or distributed, showing the amount dispensed or distributed, the date, and the name and address of the patient to whom such drugs are dispensed or distributed, except such as may be dispensed or distributed to a patient upon

Act had such scope it would certainly encounter grave constitutional difficulties" No doctor, however, who administers narcotics other than in accordance with a fair medical standard or to bona fide patients in pursuance of a bona fide medical practice can claim the Linder case as his protection The mere fact that a doctor issues a prescription is no defense if it was not a bona fide prescription, issued in the course of bona fide practice For, said the court, the purpose of the statute is "to confine the distribution of these drugs to the regular and lawful course of professional practice and that not everything called a prescription is necessarily such"

The writer expresses anew the regret which he voiced in his editorial of January first that the dissenting opinion in the Lambert case was not the opinion of the court In that dissenting opinion Mr Justice Sutherland referred to the Linder case as follows

"It is important also to bear in mind that 'direct control of medical practice in the states is beyond the power of the Federal Government' *Linder v United States*, 268 U S 5, 18 Congress, therefore, cannot directly restrict the professional judgment of the physicians or interfere with its free exercise in the treatment of diseases Whatever power exists in that respect belongs to the states exclusively"

The fact, however, that the majority of the court in the Lambert case refused to follow its previous decision in "*Linder vs United States*" is in no wise a reflection upon or repudiation of that authority The Lambert case was based solely upon the Eighteenth Amendment and all that is there said must be confined to that specific section of the Constitution Despite the fact that the Eighteenth Amendment confines its prohibition to the "manufacture, sale and transportation of intoxicating liquors *for beverage purposes*" and that the facts in that case clearly showed that the liquors sought to be dispensed were not for "beverage purposes," but for the treatment of disease, the court nevertheless sustained Congress in its regulation of the practice of medicine in so far as the prescribing of intoxicating liquors is concerned We think the majority opinion in the Lambert case was wrong and the minority was right, but of course, the majority opinion is now the law The Linder case, however, is also the law and it is gratifying and encouraging to learn and to appreciate that the practice of medicine (except as to the prescribing of intoxicating liquors) cannot be regulated and controlled in Washington except only in so far as such regulation is necessarily incident to the enforcement of a revenue measure

### CLAIMED BURN IN BAKING OF POTT'S FRACTURE

A patient was referred by an insurance company to the defendant for examination to determine the extent of the injury and disability of the patient The patient gave a history of having fallen upon the sidewalk on December 6th and sustained a Pott's fracture of the left foot At the time of the injury he was removed to the hospital where he remained two weeks, that he had been under the care of another physician The defendant's examination of the patient was made the following March 15th and baking and massage treatment advised The patient was given a baking treatment in a Biers Hyporemia by super-heated hot air Advice was also given to the patient by the physician as to active and passive motion The baker used by the physician was a standard baking apparatus electrically operated The foot was wrapped in flannel and suspended in three blankets and an asbestos sheet, making about two inches in thickness The foot and leg was then placed in the baker and the heat turned on to the required temperature The heating of the apparatus is by means of wire coils in the underpart of the baker, attached to the baker is a thermometer and the time of treatment is regulated by a clock The foot and leg up to midcalf was baked for eight minutes at a temperature of 180°, the physician

being present during the entire treatment The patient was prepared and was placed in the apparatus by the physician's nurse Upon completion of the baking, the ankle and foot of the patient were given a hand massage, cold cream being used On examination made immediately after the completion of the treatment the physician saw that there was no special reaction, the hypremia was mottled over the foot, particularly in the neighborhood of the internal malleolus and arch of the foot, which was not extensive and there was no blister or abrasion of the skin on any part of the foot or calf This was the only treatment rendered by the physician to the patient

Thereafter an action of malpractice was instituted charging that in the administration of the baking treatment the defendant physician and his nurse were negligent and careless causing the foot and leg of the plaintiff to be burned, so that it became infected and swollen, disabled him for a long period of time and caused him to procure treatment from other physicians

When the case finally came on for trial, no one appearing in behalf of the plaintiff the action was dismissed for failure of the plaintiff to prosecute the same, and a judgment of dismissal was entered in favor of the defendant

but in fact is not such. In the former case the dispensing is lawful, in the latter it is unlawful.

"What constitutes bona fide medical practice," said the court, "must be determined upon consideration of evidence and attending circumstances. Mere pretense of such practice, of course, cannot legalize forbidden sales, or otherwise nullify valid provisions of the statute, or defeat such regulations as may be fairly appropriate its enforcement within the proper limitations of a revenue measure." Of course, prescriptions fraudulently issued by a physician merely to be given away or sold to others not in the practice of the physician are condemned.

Referring to the *Jin Fuey Moy* case, in which a doctor and druggist conspired to sell opiates and in which the prescriptions were not issued in the course of professional practice and where the doctor had become a party to the prohibited sales, the court said:

"Manifestly the phrases 'to a patient' and 'in the course of his professional practice only' are intended to confine the immunity of a registered physician, in dispensing the narcotic drugs mentioned in the Act, strictly within the appropriate bounds of a physician's professional practice, and not to extend it to include a sale to a dealer or a distribution intended to cater to the appetite or satisfy the craving of one addicted to the use of the drug. A 'prescription' issued for either of the latter purposes protects neither the physician who issues it nor the dealer who knowingly accepts and fills it."

Turning again to the indictment before the court, Mr. Justice McReynolds declared that:

"It does not question the doctor's good faith nor the wisdom or propriety of his action according to medical standards. It does not allege that he dispensed the drugs otherwise than to a patient in the course of his professional practice or for other than medical purposes. The facts disclosed indicate no conscious design to violate the law, no cause to suspect that the recipient intended to sell or otherwise dispose of the drugs, and no real probability that she would not consume them."

Thus, it was held that no crime was set forth in the indictment. For, said the court, "the declared object of the Narcotic Law is to provide revenue, and this court has held that whatever additional moral end it may have in view must 'be reached only through a revenue measure and within the limits of a revenue measure.' \* \* \* Congress cannot, under the pretext of executing delegated power, pass laws for the accomplishment of objects not entrusted to the Federal Government. And we accept as established doctrine that any provision of an act of Congress ostensibly enacted under power granted by the Constitution, not naturally and reasonably adapted to the effective exercise of such power but

solely to the achievement of something plainly within power reserved to the states, is invalid and cannot be enforced."

The theory of the prosecution in the *Linder* case necessarily implied the existence of Federal power to control the practice of medicine. This the court decisely and in unequivocal language repudiated and declared:

"Obviously, direct control of medical practice in the states is beyond the power of the Federal Government. Incidental regulation of such practice by Congress through a taxing act cannot extend to matters plainly inappropriate and unnecessary to reasonable enforcement of a revenue measure. The enactment under consideration levies a tax, upheld by this court, upon every person who imports, manufactures, produces, compounds, sells, deals in, dispenses or gives away opium or coca leaves or derivatives therefrom, and may regulate medical practice in the states *only so far as reasonably appropriate for or merely incidental to its enforcement*."

To those of us who have watched with growing concern the increasing tendency of the Federal Government to reach out into the domain of the states and to gather to itself powers undreamed of by the Founders, this language of the Supreme Court is refreshing evidence that our highest tribunal is ever ready to defend the states from an unlawful encroachment upon their reserved powers by the Federal Congress. The rights of the states are guaranteed by the Tenth Amendment to the United States Constitution, which declares:

"The powers not delegated to the United States by the Constitution, nor prohibited by it to the States, are reserved to the States respectively, or to the people."

The Supreme Court in the *Linder* case has demonstrated its refusal to permit the reserved powers of the states to be broken down.

Thus, the decision in the *Linder* case is in effect that a physician who in good faith and in accordance with fair medical standards administers narcotics in moderate amounts to a bona fide patient, is performing an act which the Federal Government has no power to prevent. The mere fact that a doctor's patients may have been drug addicts does not render the doctor's act unlawful "solely because he has dispensed to one of them in the ordinary course and in good faith four small tablets of morphine or cocaine for relief of conditions incident to addiction." And the court expressly declared that there was no authority "for holding that a physician, who acts bona fide and according to fair medical standards, may never give an addict moderate amounts of drugs for self-administration in order to relieve conditions incident to addiction. Enforcement of the tax demands no such drastic rule, and if the

Address, Louis I Harris, M D—Health Commissioner of the City of New York

Technic," Lester J Unger, M D, New York City

Discussion opened by Roger H Dennett, M D, New York City

5 "The Epidemiology of Hemolytic Streptococcus Infection," Franklin H Stevens, M D, New York City (by invitation)

Discussion opened by William H Park, M D, New York City

#### PROGRAM No 11

Wednesday, May 11th, 9 30 A. M

1 "Radium Treatment of Angiomas," with lantern slides, G Allen Robinson, M D, New York City

Discussion opened by Marshall C Pease, M D, New York City, and Bernard F Schreiner, M D, Buffalo

2 "Obscure Infection as a Cause of Nutritional Disturbances in Infants," Samuel W Clausen, M D, Rochester (by invitation)

Discussion opened by Edwin S Ingersoll, M D, Rochester

3 "Tuberculosis of the Abdominal Lymph Nodes in Early Life," John L Morse, M D, Boston, Mass (by invitation)

Discussion opened by Horace LoGrasso, M D, Perrysburg

4 "The Possible Relationship Between Convulsions in Early Life and Epilepsy," William T Shanahan, M D, Sonyea

Discussion opened by DeWitt H Sherman, M D, Buffalo

#### PROGRAM No 12

Wednesday, May 11th, 2 30 P M.

1 "Cervical Adenitis," R Franklin Carter, M D, New York City

Discussion opened by Henry L K Shaw, M D, Albany

2 "Neurosurgery in the New Born and Children," William Sharpe, M D, New York City

Discussion opened by Henry W Williams, M D, Rochester

3 "The Heart in Childhood," Samuel C Smith, M D, Philadelphia, Pa (by invitation)

Discussion opened by John Aikman, M D, Rochester

4 "Heliotherapy," with lantern slides, Horace LoGrasso, M D, Perrysburg

Discussion opened by Carl G Leo-Wolf, M D, Niagara Falls

#### PROGRAM No 13

Thursday, May 12th, Clinical Day

Place of meeting, Perrysburg

Arrangements in charge of Entertainment Committee—Carl G Leo-Wolf, Chairman, Horace LoGrasso, Frank vander Bogert

"Heliotherapy and Tuberculosis," a clinical day at Perrysburg through the courtesy of Dr LoGrasso Transportation cared for by Entertainment Committee

### SECTION ON EYE, EAR, NOSE AND THROAT

Chairman  
Secretary

James W White, New York  
William A. Krieger, Poughkeepsie

*Place of Meeting, St Peter's Church, Room B*

#### PROGRAM No 14

Tuesday, May 10th, 2 30 P M

1 "Mastoiditis in Infants in Relation to Gastro-intestinal Disturbances," Edwin S Ingersoll, M D, Rochester

Discussion opened by Samuel W Clausen, M D, Rochester (by invitation)

2 "The Pathology and Treatment of Chronic Pan-Sinusitis" (Chronic Multiple Sinus Disease), Perry G Goldsmith, M D, Toronto, Canada (by invitation)

Discussion opened by Eugene E Hinman, M D, Albany

3 "Some Unusual Features of Chronic Sinusitis," Eugene E Hinman, M.D, Albany

Discussion opened by Perry G Goldsmith, M D, Toronto, Canada (by invitation)

4 "Points in the Early Diagnosis of Laryngeal Cancer with a Plea for Radical Surgical Treatment," John E MacKenty, M D, New York City

Discussion opened by Duncan Macpherson, M D, New York City

5 "The Treatment of Chronic Suppurative Otitis Media with Tubal Perforation with the Aid of the Catheterizing Eustachoscope," Case Reports, Louis K. Pitman, M D, New York City (by invitation)

Discussion opened by Samuel J Kopetzky, M D, New York City

#### PROGRAM No 15

Wednesday, May 11th, 9 30 A. M

1 "End Results in Rhinoplasty," lantern slide demonstration, Jacques Malimiak, M D, New York City

Discussion opened by Daniel S Dougherty, M D, New York City

2 "Neurology and Association with Conditions of the Eye, Ear, Nose and Throat," Foster Kennedy, M D, New York City

M D, Rochester, and Samuel J Stabins, M D, Rochester (by invitation)

Discussion opened by William W Plummer, M D, Buffalo, and Donald E McKenna, M D, Brooklyn

Wednesday, May 11, 2.30 P M

Joint session with Section on Medicine  
Place of Meeting, Niagara Hotel, Ball Room  
Program No 3 of Section on Medicine

## SECTION ON OBSTETRICS AND GYNECOLOGY

Chairman  
Secretary

Hugh C McDowell, M D, Buffalo  
Nathan P Sears, M D, Syracuse

*Place of Meeting, St Peter's Church, Room C*

### PROGRAM No 7

Tuesday, May 10th, 2.30 P. M

1 "Uterine Bleeding—A Clinical and Pathological Interpretation," Meyer R Robinson, M D, New York City

Discussion opened by Earl P Lothrop, M D, Buffalo, and Bernard F Schreiner, M D, Buffalo

2 "Unusual Tumors of New-Born," Benjamin Roman, M D, Buffalo

Discussion opened by Herbert U Williams, M D, Buffalo, and William F Jacobs, M D, Buffalo

3 "Certain Pathological Conditions of the Cervix Uteri Tending toward Cancer," James N West, M D, New York City

Discussion opened by George R Critchlow, M D, Buffalo, and Burton T Simpson, M D, Buffalo

4 "Sloane Maternity," William E Caldwell, M D, New York City

### PROGRAM No 8

Wednesday, May 11th, 9.30 A. M

1 "Urinary Disturbances in Women, Causes and Treatment—A Study of 500 Consecutive Cases," Frederick T Lau, M D, New York City

Discussion opened by Oscar J Oberkircher, M D, Buffalo, and Dr Watson

2 "Pelvic Sepsis—A Plea for Delayed Operative Intervention," James B Ricci, M D, New York City

Discussion opened by Francis M O'Gorman, M D, Buffalo

3 "Cesarian Section," William T Getman, M D, Buffalo

Discussion opened by James K Quigley, M D, Rochester

4 "Gwathmey Anesthesia—Report 100 Cases," William H McKay, M D, Buffalo

### PROGRAM No 9

Wednesday, May 11th, 2.30 P M

1 "The Incompletely Dilated Cervix," Paul T Harper, M D, Albany

Discussion opened by Irving W Potter, M D, Buffalo

2 "Placenta Ecreta," Delbert L Jackson, M D, Boston (by invitation)

Discussion opened by Francis C Goldsborough, M D, Buffalo

3 "End Results in Procidencia Operation," Frank A Pemberton, M D, Boston (by invitation)

Discussion opened by James E King, M D, Buffalo

## SECTION ON PEDIATRICS

Chairman  
Secretary

Arthur W Benson M D, Troy  
John Aikman, M D, Rochester

*Place of Meeting, Knights of Columbus, Room B*

### PROGRAM No 10

Tuesday, May 10th, 2.30 P M

1 "Fatigue in Children," George R Irving, M D, New York City

Discussion opened by Frank vander Bogert, M D, Schenectady

2 "The Nervous Child," Frank H Richardson, M D, Brooklyn

Discussion opened by Frankwood E Williams, M D, New York City

3 "Some Prognostic Values in Measurement of Intelligence," Ira S Wile, M D, New York City

Discussion opened by ————

4 "Indications and Results of Blood Transfusion with Motion Pictures of Author's

- 2 "Meningeal Reactions Following Trauma,"  
Edward A. Sharp, M.D., Buffalo
- 3 "Headache and Glandular Therapy,"  
Timothy F. Donovan, M.D., Buffalo (by invitation)

PROGRAM No 20

Wednesday, May 11th, 2:30 P. M.

- 1 "Present Day Social Care of Epileptic Patients," Thomas K. Davis, M.D., New York City
- 2 "Relation of Vitamines to Neurology," John M. McKinney, M.D., New York City

SECTION ON DERMATOLOGY AND SYPHILOLOGY

Chairman  
Secretary

Howard Fox, M.D., New York  
Earl D. Osborne, M.D., Buffalo

*Place of Meeting, Niagara Hotel, Parlor D*

PROGRAM No 21

Tuesday, May 10th, 2:30 P. M.

- 1 "Points of Contact Between Dermatology and Other Branches of Medicine," Charles M. Williams, M.D., New York

- 2 "Industrial Cancer," George C. Andrews, M.D., New York

- 3 "Dangers of Metastases from Incomplete Removal of Malignancies of the Skin," Albert R. McFarland, M.D., Rochester

Second and Third Papers will be discussed together. Discussion opened by Burton T. Simpson, M.D., Buffalo

- 4 "The Capacity of Dermatology," William Allen Pusey, M.D., Chicago, Ill. (by invitation)

- 5 "Studies in Mycotic Dermatitis. I. Superficial Yeast Infections of the Glabrous Skin," Cleveland J. White, M.D., Buffalo

Discussion opened by J. Gardner Hopkins, M.D., New York

- 6 "Cosmetics, Composition, Dermatoses, Treatment," Lawrence K. McCafferty, M.D., New York, and Serafino Genovese, M.D., New York
- Discussion opened by S. Dana Hubbard, M.D., New York

- 7 "Arsenic Findings in Dermatological Conditions," Binford Throne, M.D., Brooklyn

Discussion opened by Earl D. Osborne, M.D., Buffalo

PROGRAM No 22

Wednesday, May 11th, 9:30 A. M.

- 1 "Pigeon Hole Dermatology," Walter J. Highman, M.D., New York

- 2 "Vincent's Spirochete as a Cause for Genital Infections," Lt. Col. M. A. Reasoner, New York (by invitation)

Discussion opened by Charles A. Bentz, M.D., Buffalo

Symposium on Syphilis

- 3 "The Role of the Darkfield in the Diagnosis of Syphilis," Josiah P. Thornley, M.D., New York

- 4 "Syphilis and Its Recognition and Care from an Industrial Standpoint," William E. Low, Jr., M.D., Johnson City

- 5 "Standardized Treatment in early Syphilis as a Means of Eliminating Neurosyphilis," A. Benson Cannon, M.D., New York

The third, fourth and fifth papers will be discussed together

Discussion opened by Mihran B. Parounagian, M.D., New York

- 6 "The Pathology of Urticaria Pigmentosa," J. Frank Fraser, M.D., New York, and Maurice N. Richter, M.D., New York (by invitation)

- 7 "Experimental Urticaria, Wheals Induced Through Internal Channels," Abraham Walzer, M.D., Brooklyn, and Matthew Walzer, Brooklyn

The sixth and seventh papers will be discussed together

Discussion opened by David L. Satenstein, M.D., New York

PROGRAM No 23

Wednesday, May 11th, 2:30 P. M.

- 1 "Parapsoriasis, Suggestions for simplifying Nomenclature and Classification of Clinical Varieties for Teaching Purposes," Fred Wise, M.D., New York

Discussion opened by Louis B. Mount, M.D., Albany

- 2 "The Atypical Form of Neurofibroma," Oscar L. Levin, M.D., New York

Discussion opened by Walter J. Highman, M.D., New York

Symposium on Treatment of Skin Diseases

- 3 "Chemotherapy in Diseases of the Skin," Paul E. Bechet, M.D., New York

- 4 "Phototherapeutics of Dermatology, Basic Underlying Principles and Application," Herman Goodman, M.D., New York

- 5 "The Internal Treatment of Skin Diseases," E. William Abramowitz, M.D., New York

- 6 "Radium Therapy in Certain Skin Lesions," Earl L. Eaton, M.D., Buffalo

- 7 "The Prevention and Treatment of Acne Vulgaris," Herbert H. Bauckus, M.D., Buffalo

The third, fourth, fifth, sixth and seventh papers will be discussed together

Discussion opened by Edward R. Maloney, M.D., New York

Discussion opened by John L. Eckel, M D, Buffalo

3 "Headache," Robert G. Armour, M D, Toronto, Canada (by invitation)

Discussion opened by Arthur J. Bedell, M D, Albany, David E. S. Wishart, M D, Toronto, Canada (by invitation), and Andrew A. Fletcher, M D, Toronto, Canada (by invitation)

#### PROGRAM No 16

Wednesday, May 11th, 2 30 P M

1 "The Value of Scotometry in the Diagnosis and Treatment of Glaucoma," Aaron H. Thomasson, M D, New York City

Discussion opened by Conrad Berens, M D, New York City

2 "Non Surgical Treatment of Glaucoma," Searle B. Marlow, M D, Syracuse.

Discussion opened by Albert C. Snell, M D, Rochester

3 "Non Operative Treatment of Cataract with Report on Lens Antigen Treatment," John M. Wheeler, M D, and Zenas H. Ellis, M D, New York City

Discussion opened by A. Edward Davis, M D, New York City

4 "Two Safety Measures in Cataract Extraction," Walter S. Atkinson, M D, Watertown

Discussion opened by Harold H. Joy, M D, Syracuse

### SECTION ON PUBLIC HEALTH, HYGIENE AND SANITATION

COMBINED SESSION WITH

### THE NEW YORK STATE SOCIETY OF INDUSTRIAL HYGIENE

AND THE

### SECTION ON INDUSTRIAL MEDICINE

*Place of Meeting, St. Peter's Church, Room A*

Sessions, Tuesday, 9 30 A M

Tuesday, 2 00 P M

Wednesday, 9 30 A M

See Programs 24, 25 and 26

#### PROGRAM No 17

Wednesday, May 11th, 2 30 P M

*Place of Meeting, St. Peter's Church, Room A*

1 "Rabies and Its Control," Veranus A. Moore, M D, Dean, N Y State Veterinary College, Ithaca

Discussion opened by Richard Slee, M D, White Plains

2 Series of five-minute subjects for round table discussion

(a) "Report on 1927 Health Legislation," Paul B. Brooks, M D, Albany

(b) "Correction of Physical Defects in School Children," Davis C. McKenzie, M D, Granville

(c) "Discussion on Methods for Obtaining Correction of Physical Defects in School Children in Rural Communities," Frederick W. Sears, M D, Syracuse

(d) "Generalized Nursing Program in City Departments of Health," John H. Collins, M D, Schenectady

(e) "County Health Unit, Its Relations to the Medical Profession," Stephen A. Douglass, M D, Olean

(f) "Tuberculosis Reporting How to Better It," George C. Ruhland, M D, Syracuse

(g) "City Scoring Its Worth," Edwin G. Ramsdell, M D, White Plains

### SECTION ON NEUROLOGY AND PSYCHIATRY

Chairman  
Secretary

Herman F. May, M D, Buffalo  
Thomas K. Davis, M D, New York

*Place of Meeting, Niagara Hotel, Parlor A*

#### PROGRAM No 18

Tuesday, May 10th, 2 30 P M

1 "The Mental Hygiene Situation in New York State," Frederick W. Parsons, M D, Albany

2 "A Case of Tabes with an Unusual Complication of Marked Muscular Atrophy," Edward Livingston Hunt, M D, New York City

3 "Results of Malarial Treatment in First One Hundred Patients at Buffalo State Hospital," Hyman L. Levin, M D, Buffalo

#### PROGRAM No 19

Wednesday, May 11th, 9 30 A M

1 "Does Psychiatry Need Help?" Herman G. Matzinger, M D, Buffalo

vention that will be Loaned by the American Society for the Control on Cancer John M Swan, M D, Rochester, State Chairman, American Society for the Control of Cancer

#### PROGRAM No 28

Afternoon Session—Talks

Place of Meeting, Knights of Columbus Home, Room A

Etiology of Cancer—Burton T Simpson, M D, Buffalo, Director State Institute for the Study of Malignant Disease, Buffalo

Discussion opened by Herbert A Smith, M D, Buffalo

Cancer Research—William H Woglom, M D, New York City, Institute of Cancer Research of Columbia University

Discussion opened by Burton T Simpson, M D, Buffalo

Diagnosis and Prevention of Cancer—Isaac Levin, M D, New York City, Director New York City Cancer Institute, New York

Discussion opened by William D Johnson, M D, Batavia

Treatment of Cancer—Bernard F Schreiner, M D, Buffalo, State Institute for the Study of Malignant Disease, Buffalo

Discussion opened by Douglas Quick, M D, New York City

---

### ENTERTAINMENTS FOR THE DOCTORS

Golf tournament at Fort Hill Golf Club This is a very sporty golf course All doctors desiring to play in the tournament should make applica-

tion for assignments to Dr Carl G Leo-Wolf, Chairman, 108 Buffalo Avenue, Niagara Falls, N Y

---

### ENTERTAINMENTS FOR LADIES

*Mrs W H Hodge, Hostess*

*Assistant Hostesses*

Mrs C G Leo-Wolf  
Mrs A L Chapin  
Mrs Walter Scott  
Dr Beatrice Smith  
Mrs E L Burhyte  
Mrs G P Eddy  
Mrs F H Towne  
Mrs E E Gillick  
Mrs Elbert Ingram

Mrs E A Palmer  
Mrs R H Sherwood  
Mrs Frederick Schnell  
Mrs G L Miller  
Mrs Oscar Baer  
Mrs Frederick Leighton  
Mrs L M Jane  
Mrs W Roger Scott  
Mrs H U Cramer

---

#### TUESDAY AFTERNOON

Bridge Tea, Shredded Wheat Auditorium  
(By courtesy of the Shredded Wheat Co)

*Hostesses*

Mrs E L Burhyte  
Mrs G P Eddy

---

#### WEDNESDAY MORNING

Golf, Lewiston Heights Country Club

*Hostess*

Mrs F H Towne

---

#### WEDNESDAY AFTERNOON

Automobile ride to Fort Niagara, Reception by Col Ingram, Commander of the Fort, and talk by

him on the History of the Fort, followed by tea at the Lewiston Heights Country Club

*Hostess*

Mrs A L Chapin

2 "Health Hazards Due to Factory Atmosphere," C. E. A. Winslow, M.D., Yale University, School of Medicine

Discussion opened by William A. Sawyer, M.D., Rochester

3 "A Study of Cancer Death Rate Variations, Combustion Products of Fuel, Topography and Population," Jerome Meyers, M.D., New York City

4 "Epidemiology of Whooping Cough," Edward S. Godfrey, Jr., M.D., Albany

## CANCER DAY—MAY 12th

### MORNING SESSION—DEMONSTRATION

Committee on Cancer Demonstration: Burton T. Simpson, Chairman, Harley U. Cramer, Bernard F. Schreiner, Alvin G. Foord, William F. Jacobs, Marshall Clinton, Francis M. O'Gorman and A. A. Thibaudau, M.B.

*Place, Niagara Hotel, Ball Room*

**PROGRAM No 27**

Gross Pathology—Demonstration of Various Types of Tumors. Courtesy of Buffalo City Hospital. William F. Jacobs, M.D., and Alvin G. Foord, M.D., Buffalo

Microscopic Pathology—Alvin G. Foord, M.D., William F. Jacobs, M.D., and Burton T. Simpson, M.D., Buffalo

Demonstration of Rapid "Table" Diagnosis by Means of Frozen Sections, Alphonse A. Thibaudau, M.B., Buffalo, Miss Irma Miller and Eugene Burke

Demonstration of Methods of Cancer Research

Mr. Millard C. Marsh, Biologist, State Institute for the Study of Malignant Disease, Buffalo

Demonstration of Clinical Cases and X-ray Films, Isaac Levin, M.D., Director, New York City Cancer Institute. Bernard F. Schreiner, M.D., Buffalo, Surgeon, State Institute for the Study of Malignant Disease, Buffalo

Demonstration of Radium Appliances. Radium Chemical Company, Pittsburgh, Pa.

Moving Pictures Showing Treatment by Endothermy. George A. Wyeth, M.D., New York City

Moving Picture Showing Films on Cancer Pre-

tion, to fighting individual diseases. These organizations have been of inestimable value in influencing public opinion and in supporting the governmental agencies in public health. Endowments for educational purposes now aggregate one billion dollars, much of which is used to educate physicians for private practice. There are also organizations devoted to public health work, such as the Rockefeller Foundation and the Milbank Fund. Others, such as the National Tuberculosis Association, depend on voluntary subscriptions. While some organizations support medical research work, others are directed to the education of the public and the stimulation of governmental activity. We shall probably never develop official preventive work to such an extent as to eliminate the voluntary non-official organizations. While the endowments made by private persons to support non-official health organizations may have sometimes acted unwisely, yet there is a marked tendency toward consolidation and cooperation, and the adoption of enlightened methods.

"The medical profession has also passed through an evolution from a scattered few physicians, individualistic and far-seeing, up to the present organized guilds, culminating in the American Medical Association.

"The public has recognized the dignity and importance of physicians and has thrown around the permission to practice medicine intellectual and educational requirements higher than those of any other profession. The increased knowledge of disease is such that its possession and application are beyond the capacity of any individual, and so cooperation is necessary.

"The best medical services are beyond the financial ability of a large proportion of the people, and are furthermore not everywhere available, especially in rural districts. Nor has the medical profession always appreciated its duty to the public in education in preventive medicine.

"Official health organizations have developed from skeleton groups of part-time doctors organized for suppressing epidemics, to highly organized departments which have entered the field of preventive medicine in such activities as universal vaccination, the examination of specimens for diagnosis, and the manufacture of laboratory products. Free clinics have been established, and demonstrations have been conducted by non-official organizations.

"The problem of preventive medicine would seem to involve the "Eternal triangle"—the public, the health official, and the practicing physician. It may even be quadrangular if we divide health workers into official and non-official. But physicians as a class have not appreciated their obligation to the public in public health, particularly in health education, but this condition is being remedied under the leadership of the

American Medical Association. Public health workers, both official and non-official, have extended their field of activity beyond prevention so that they now include the improvement of the physical and mental efficiency of the individuals which compose the public. Some workers are sometimes discouraged by the ignorance and indifference of the public, but yet the people are being aroused to the importance of health. The question is no longer approached solely from ethical and humanitarian motives, but from the economic standpoint, as is shown by the health work of great business corporations.

"A larger part of non-medical public health work is now being done under the direction of non-medical men. If physicians are not aroused to the importance of public health work, and do not wisely guide and assist the public, we shall have attempts at the socialization of medicine, such as are made in other countries. The physician owes a duty to the public as its counsellor and guide. The discharge of that duty lies with the local physicians in each community.

"The duty of the physician to the public should be taught in medical schools. The local medical societies should see that the public health officers are taken out of partisan politics, that competent public health officials are chosen, that adequate appropriations are made for public health, and that moral and active assistance is given to local health officials.

"It is unheard of that a health officer should complain of the intrusion of the private practitioner in his field of activity. While certain fields of activity may be covered by the state, yet new fields are opening to physicians.

"The science of medicine can no longer be restricted within the confines of the medical profession. The biochemist, the sociologist, the physicist, the sanitary engineer, and the worker in pure science, must all be included in public health. The cure and prevention of tuberculosis, for example, is as much an economic problem as a medical one. Even in private practice the doctor must rely on non-medical and technical assistants and ultimately depend for his remedies either upon the state or commercial enterprises under state supervision. No longer can we speak of voluntary action being separate from the official, for the action of the official is the expression of the wish of the people.

"It will be impossible to delimit the respective fields of the private practitioner and the public health official in specific terms appropriate to the whole country.

"The people as a whole appreciate the value of health and the method of obtaining it, but they are more or less indifferent how this end shall be accomplished. It is the privilege of physicians to cooperate with the public and its duly appointed representatives in the development of

## AMERICAN MEDICAL ASSOCIATION CONFERENCE ON PUBLIC HEALTH

A Conference on Public Health was held on March 24 and 25 in Chicago under the auspices of the American Medical Association, in the building of the Association. Over seventy representatives of societies engaged in public health were in attendance. New York was represented by Dr Wendell C Phillips, President of the American Medical Association, who presided, Dr Harlow Brooks, representative of the physicians of New York City, who presented one of the leading papers before the Conference, Dr George M Fisher, President of the Medical Society of the State of New York, Dr Frank Overton, Executive Editor of the *NEW YORK STATE JOURNAL OF MEDICINE*, Dr Francis Carter Wood, Director of the Crocker Foundation for Cancer Research of the College of Physicians and Surgeons, Dr Matthias Nicoll, Jr, State Commissioner of Health, Dr Linsly R Williams, Director of the National Tuberculosis Association, Dr Donald B Armstrong, representative of the medical service of the Metropolitan Life Insurance Company, Dr Lyman Fisk, Director of the Life Extension Institute, Mr Homer Folks, Secretary of the State Charities Aid Association, Mr John A Kingsbury of the Milbank Fund, and Mrs W B Meloney, Editor of the Sunday Magazine of the *New York Herald Tribune*. The majority of those in attendance were specialists in public health.

The printed program consisted of three sessions with nine papers. The session on the morning of the 24th was on the relation of the physicians to public health, and this subject dominated the other two. The afternoon session was on public health education, and that on the following morning was on the statistics of expenditures by official departments of health. Those in attendance were guests of the American Medical Association at supper in the evening in the Hotel Virginia.

Regarding the relations of the medical profession to public health, much was said by way of diagnosis of general difficulties and misunderstandings between family doctors and lay organizations. As for treatment, considerable was said in a general way about the duty of family doctors to engage in public health work, but almost the only concrete suggestion was that of Dr Fisher who recommended a trial of the plan of the Committee on Public Relations of the New York State Medical Society.

Dr Wendell C Phillips, in opening the Conference, said that the object of the Conference was to promote mutual understanding and team work between the general practitioners of medicine and public health workers. Physicians should do more work of a preventive nature, especially in advice in personal hygiene. They

should treat the patient rather than his disease. The American Medical Association is seeking to educate the public by means of its magazine *Hygeia*, and by clip sheets of the *JOURNAL* sent to a long list of newspapers throughout the nation.

Dr Olin West, General Manager of the American Medical Association, introduced the heads of the divisions of the Association, who each described his work briefly.

The first paper was by Dr Hugh S Cumming, Surgeon General, U S Public Health Service. "Public health," he said, "has been a governmental function from the earliest times, as is evidenced by public water works and baths, and various official positions established by Greek and Roman governments for maritime quarantines, and the segregation of lepers, and the Hebrew and Egyptian laws relating to hygiene."

"Ecclesiastical orders and institutions for the care of the sick were the beginnings of non-official public health work, but they were for the relief of suffering rather than its prevention. It was not indifference that led to neglect of prevention, but rather the ignorance of what to do."

"Modern preventive work began in Great Britain in the 17th Century as the result of industrial development, and was a governmental function with non-official bodies acting in an educational way. Prevention in the United States at first was largely environmental, such as the suppression of contagious diseases and the control of water and milk. But Federal control was mostly local except in large matters, such as protection against yellow fever. Modern public health activities were made possible by the epochal discoveries in bacteriology. As the searchlight of science was thrown into the misty darkness, the hopeless and blind efforts against contagions gave way to intelligent conquest, and the army of physicians, who had hitherto stood alone in its fight against diseases, was joined by allies, such as the sanitary engineer, the laboratory worker, and the social economists."

"The role of the family physician in public health work consists in his wise guidance of the opinions of his fellow citizens in securing adequate public health organizations in his community, county, and state, and in the correct diagnosing and reporting of contagious diseases. But his activities here have been hampered by mistaken notions of professional ethics and a dislike of political activity."

"A development, unique and almost peculiar to this country, has been that of non-official organizations devoted to various phases of improvement of the people from general welfare educa-

tion, to fighting individual diseases. These organizations have been of inestimable value in influencing public opinion and in supporting the governmental agencies in public health. Endowments for educational purposes now aggregate one billion dollars, much of which is used to educate physicians for private practice. There are also organizations devoted to public health work, such as the Rockefeller Foundation and the Milbank Fund. Others, such as the National Tuberculosis Association, depend on voluntary subscriptions. While some organizations support medical research work, others are directed to the education of the public and the stimulation of governmental activity. We shall probably never develop official preventive work to such an extent as to eliminate the voluntary non-official organizations. While the endowments made by private persons to support non-official health organizations may have sometimes acted unwisely, yet there is a marked tendency toward consolidation and cooperation, and the adoption of enlightened methods.

"The medical profession has also passed through an evolution from a scattered few physicians, individualistic and far-seeing, up to the present organized guilds, culminating in the American Medical Association.

"The public has recognized the dignity and importance of physicians and has thrown around the permission to practice medicine intellectual and educational requirements higher than those of any other profession. The increased knowledge of disease is such that its possession and application are beyond the capacity of any individual, and so cooperation is necessary.

"The best medical services are beyond the financial ability of a large proportion of the people, and are furthermore not everywhere available, especially in rural districts. Nor has the medical profession always appreciated its duty to the public in education in preventive medicine.

"Official health organizations have developed from skeleton groups of part-time doctors organized for suppressing epidemics, to highly organized departments which have entered the field of preventive medicine in such activities as universal vaccination, the examination of specimens for diagnosis, and the manufacture of laboratory products. Free clinics have been established, and demonstrations have been conducted by non-official organizations.

"The problem of preventive medicine would seem to involve the "Eternal triangle"—the public, the health official, and the practicing physician. It may even be quadrangular if we divide health workers into official and non-official. But physicians as a class have not appreciated their obligation to the public in public health, particularly in health education, but this condition is being remedied under the leadership of the

American Medical Association. Public health workers, both official and non-official, have extended their field of activity beyond prevention so that they now include the improvement of the physical and mental efficiency of the individuals which compose the public. Some workers are sometimes discouraged by the ignorance and indifference of the public, but yet the people are being aroused to the importance of health. The question is no longer approached solely from ethical and humanitarian motives, but from the economic standpoint, as is shown by the health work of great business corporations.

"A larger part of non-medical public health work is now being done under the direction of non-medical men. If physicians are not aroused to the importance of public health work, and do not wisely guide and assist the public, we shall have attempts at the socialization of medicine, such as are made in other countries. The physician owes a duty to the public as its counsellor and guide. The discharge of that duty lies with the local physicians in each community.

"The duty of the physician to the public should be taught in medical schools. The local medical societies should see that the public health officers are taken out of partisan politics, that competent public health officials are chosen, that adequate appropriations are made for public health, and that moral and active assistance is given to local health officials.

"It is unheard that a health officer should complain of the intrusion of the private practitioner in his field of activity. While certain fields of activity may be covered by the state, yet new fields are opening to physicians.

"The science of medicine can no longer be restricted within the confines of the medical profession. The biochemist, the sociologist, the physicist, the sanitary engineer, and the worker in pure science, must all be included in public health. The cure and prevention of tuberculosis, for example, is as much an economic problem as a medical one. Even in private practice the doctor must rely on non-medical and technical assistants and ultimately depend for his remedies either upon the state or commercial enterprises under state supervision. No longer can we speak of voluntary action being separate from the official, for the action of the official is the expression of the wish of the people.

"It will be impossible to delimit the respective fields of the private practitioner and the public health official in specific terms appropriate to the whole country.

"The people as a whole appreciate the value of health and the method of obtaining it, but they are more or less indifferent how this end shall be accomplished. It is the privilege of physicians to cooperate with the public and its duly appointed representatives in the development of

a satisfactory system of attaining health, and it would be unfortunate to give the public any other impression

"The medical profession has always been regarded as the natural sponsor, not only of individual but also of community health. Whether this service in the future shall be rendered by the profession in cooperation with health authorities, or be made incumbent on the legal health representatives must depend on the character of the service rendered by the profession. It is the object of the organized profession to impress upon each individual physician his responsibility in this matter."

Dr Arthur T Holbrook, Milwaukee, discussed the relations of the physician to public health in the city of medium size, such as Milwaukee, and said "Personal contact is the characteristic of public health work in the smaller city as distinguished from that in a city of major size. Physicians and public health workers know one another, and can readily smooth out their differences and reach agreements."

"If one hundred private practitioners were to pick up a journal containing an article with the title of this address, at least eighty-five would pass it by. Eight would be those who consistently read their medical journals from cover to cover, and the other seven would include specialists in public health. This expresses the lack of personal responsibility for public health on the part of the average physician. Yet every one of the eighty-five doctors would argue earnestly in favor of the public health program, but when it comes to concrete performance, he leaves action to officials. He does not attend public hearings on questions of community health, he joins some of the allied societies but does not attend the meetings, he favors public clinics but cannot tell where they are located. He is like the Christian who never goes to church. How is this physician to acquire the idea that every practitioner of medicine who is granted a license has a definite obligation to the state, and that it is his duty to assist in the work of the health department? If he lives in New York State, the sanitary code of his state points out some of these duties."

"The medical profession leaves the work of the allied health organizations too much in the hands of the laity. There would be less criticism of these organizations if doctors sought membership in them, and took an active part in their proceedings."

"Now what may a physician of a small city expect of the public health workers? First of all, he expects that the officials shall be scientifically trained men, free from political influence. The medical societies can do much to bring this about."

"Second, physicians have a right to know defi-

nately the attitude of the health officer toward medical practice in the community. He will insist on the proper control of dispensaries and clinics, on cooperation in the city hospitals, and on the reference of cases back to the attending doctor. Practically all health officers are cooperating with the doctors."

"Third, he expects the cooperation of the health officer in the control of cases of communicable diseases, but in this matter the doctor is uncooperative more often than the health officer."

"Fourth, doctors expect the health department to take the leadership in the exposure of quacks."

"The fear that public health administration will deprive deserving physicians of a competent livelihood is groundless."

"It is a fallacy to try to define the exact and separate responsibilities of preventive as distinguished from curative medicine."

"The relations of physicians to health departments has been well handled by Dr John P Koehler, Health Officer of Milwaukee. He has an advisory committee of fourteen members, consisting of six physicians and eight laymen. The efficient work of this representative committee has earned for it the title 'The Unofficial Guardians of the City's Health'."

Dr Frank W Cregor, of Indianapolis, spoke from the standpoint of a doctor who had gone through the varied experience of a rural practitioner, who had moved to a village and then to a large city, and had become a specialist in practice, and during his entire career had been identified with his local health departments and public health work."

Dr Cregor first spoke of the manner of selecting a health officer by lay boards, and urged the societies of physicians to take an active interest in securing properly qualified men for the position."

"Medical practice presupposes individual service," he said, "and yet the medical profession is the one body qualified to do public health work. Potentially the physician engaged in public health work reflects the attitude of the profession. This attitude is nearly always correct in the abstract, but is often rather narrow and biased concretely."

"When new problems arise in departments of health, it is the part of wisdom to consult the medical societies and get the support of doctors before trying to promote something for which the doctors are not prepared."

"The architecture for the health organization is probably as good as it can well be made, but its structure can be improved. One element of added strength would be close cooperation with organizations of physicians. Physicians need their organizations and health departments, and

to use them as means of discharging their civic obligations."

Dr Harlow Brooks, of New York City, spoke from the viewpoint of a medical man practising in one of the great cities, and said "The invitation has come to me to speak on some points in which the doctor might not be in complete sympathy with the activities of lay organizations engaged in public health work. Doctors must consider as professional workers equal with themselves all those who in hygiene, bacteriology, pathology, anatomy, physiology, and therapeutics have equalled the requirements of a class A medical college in these subjects. But we have a quite natural suspicion of those lawyers, politicians, business men and preachers, who have had no basic training in medical or allied subjects.

"I was astonished the other day to read the statement of a worker in public health that the medical profession was often found in conflict with public health authorities. I cannot understand such a position unless the public health service in that instance was interested, as are some of the lay organizations, in activities basically contrary to the teachings of medical science.

"The absurd accusation has been made that the medical man is not interested in the prevention of sickness, but only in its alleviation. The family doctor is, and always has been, the very bone and sinew of all successful methods for the prevention of disease. Bitter experience has taught him to view with much caution the emanations of untramed, unthinking, irresponsible dabblers in health and medical practice. He is slow to accept unreasonable theories, or to contract the hysteria which is likely to develop in every epidemic.

"The accusation has also been made that the medical practitioner is not public spirited, not a nationalist—thus of a profession which gave twenty per cent of its personnel, old and young, in a great national calamity, of a profession whose members are acting on the board of every educational advance, church, and charitable venture, a profession which has always identified itself in every good project of humanity. There are those who feel that hospitals would be beautifully efficient institutions if only there were no doctors to demand that business step aside for welfare of the sick, and that organized charity reach the unfortunate instead of spending its efforts and funds on a perfect business institution.

"Criticisms of the types just mentioned originate largely from the activity of what General Harbord calls the 'pathogenic bacillus' known as the paid executive secretary. He has never flourished in the culture medium supplied by the medical profession. As to the justification of the criticisms, it is too true that there are a few who despise the code of ethics, fail to read medical journals and to attend medical meetings, and

do not try to keep abreast of the times. Some few even make their profession a business and die rich. But these are the exceptions and are not representative of the great mass of physicians who value their professional standards higher than life itself.

"Misunderstandings have arisen between the medical profession and some worthy public health activities. Was there ever progress without argument or criticism? There is little or no criticism of those activities controlled by the United State Public Health Service or those of the Departments of Health of the states and cities. Misunderstandings with social activities in public health have nearly always originated when physicians have been asked to forget their scientific training, or when their code of ethics has been ignored. Medical ethics apply to public health as strongly as to any other medical specialty.

"Now, let us consider what the family physician says of the public health worker. In the first place, he resents nurses doing the work of physicians—making diagnoses and dictating the treatment which the family doctor shall carry out.

"He resents the underpaid, time-serving employee who minimizes to school children the work of the family doctor. He resents the snap diagnosis of an employee on a case to which he has given serious and experienced study.

"He resents being directed in the institution of treatments which he knows, from his journals and societies, to be still in the experimental stage.

"This is all easily correctable, both as to the nurses and to the physicians employed in public health work. Employment of young physicians at meager salaries robs the profession of the material from which it should recruit its general practitioners, now the greatest need of the profession. I often tell my internes as they graduate that the worst thing which can happen to them is to receive a salary on which they can live, from some lay institution, in which the resulting professional experience does not reward the service, for many of them later on do not dare to give up their salaries and start out for themselves. Some of the brightest youngsters I have known have been ruined by such activities. They typify the business and non-professional controlled society.

"Another matter in the control of professional institutions by laymen lies in the demands made on the young men for services inadequately repaid either by the experience which they gain, or by the pay which they receive. Many privately controlled hospitals are sinners in this matter. Some are notorious for their ruthless but entirely business-like exploitation of the young physician.

"Wealth under the guise of charity and public

progress more than seldom dominates even medical education. High endowments without professional control have dwarfed medical teaching in more than one institution.

"Public medicine cannot be divorced from private medicine except at a loss by both. The most potent and influential teacher of public medicine and of practice is the physician in contact with his patient.

"The value and the influence of the average practitioner is beyond the comprehension of the executive who is himself not conversant with the details of medical practice, or who has through lack of experience so estranged himself from his profession and its practitioners that he fails to comprehend even its purposes. He is likely to develop a superiority complex of a peculiarly inexcusable type. This is the disease from which many public health workers suffer—they are those who criticize the average doctor.

"A recent number of the *Atlantic Monthly* carried a just arraignment of the control of medical education by self-perpetuating bodies, such as the general education board. This same subject was discussed in an editorial, "The Perils of Magnanimity," in the *Journal of the A M A* of March 5th. The *Journal of the A M A* for February 12th also has an editorial on "The Physician's Responsibility in Preventive Medicine," which physicians generally approve.

"It is a simple matter to readjust our differences and to bring to us the whole-hearted support of the people. Let us acquaint them with our purposes and invite them into our confidence. Let us give our ideas to the public press. Remember, however, that every one of our people has his doctor, and that he does not have any higher opinion of the medical profession than his own doctor. We and our reputation in every respect are absolutely in the hands of the practicing physician. May it never be otherwise!

"What constructive suggestions can the American Medical Association offer? The medical profession is ready to accept the following activities:

"1. The Association shall take the lead in the control of its own members. It and not the zealous amateur shall set the standard in the education, our position in this nation, and even our discussion of medical matters.

"2. The national, state and county societies shall enlist every member in the work of public health, shall invite the cooperation of lay bodies, but shall insist on medical standards and ethics.

"3. The medical organizations shall detail lecturers on health for public occasions, and give to the press health news and instruction.

"4. Medical organizations shall teach students and young practitioners the essentials of public health as we now teach them an outline of medicine, therapeutics, and surgery.

"5. Medical organizations shall uphold the

ideal expressed by Dr. George Vincent, 'Every doctor a health officer'."

Mr. Homer Folks, Secretary of the New York State Charities Aid Association, the typical lay health organization of New York State, answered Dr. Brooks and said he was surprised at the trend, spirit and tone of his remarks. He said that he had not met Dr. Brooks at the board meetings of any of the lay organizations, and so he could not see how the doctor got his impressions.

Mr. Folks explained that all lay health organizations are advised and directed by physicians, and that the State Charities Aid Association has the President of the Medical Society of the State of New York on its Board of Managers. When the doctors had given the lay organizations concrete advice, it had been adopted. The lay organizations had agreed with medical men when the representatives of the two organizations had sat down together and discussed their mutual problems.

Mr. John A. Kingsbury, speaking for the Milbank demonstration in Cattaraugus County, said that the leaders of the demonstration had brought the matter before the County Medical Society, and that only ten members were present. Mr. Kingsbury had been able to secure the endorsement of the ten who attended the meeting, but the difficulty since that time has been to reach the fifty or more who did not attend the meeting.

Dr. Donald B. Armstrong, representing the educational work of the Metropolitan Life Insurance Co., stressed the importance of teaching the people personal hygiene.

Dr. George M. Fisher, President of the Medical Society of the State of New York, told of the work of the Committee on Public Relations which is composed of an equal number of representatives of the State Medical Society and of the State Charities Aid Association. It had held several meetings, and discussed problems of overlapping activities and cooperations. He said that the prospect is that the Committee will smooth out present differences, and prevent future misunderstandings.

Dr. Fisher suggested that the American Medical Association appoint a committee similar to the Public Relations Committee of New York State, and that it should act on problems of a national scope. This suggestion was approved by those present at the meeting.

Dr. Henry F. Vaughan, Health Officer of Detroit, said that it would be a mistake if the meeting should adjourn without devising a common meeting ground which should begin at the American Medical Association and set a standard of procedure that could be followed by the workers down to the smallest units in the counties.

Dr. Linsly R. Williams, Director of the National Tuberculosis Association, described the

methods of the Association, and emphasized the policy of the Association to consult the local doctors in their plans

Following his paper there was some criticism of the methods of the State Associations of Tennessee and Alabama where the wishes of the local physicians were not followed. Dr. Williams replied that the National organization always worked with the local doctors, and he regretted his inability to control the unwise actions of representatives of subordinate groups.

The second topic of discussion was public health education. Dr. Matthias Nicoll, Jr., Commissioner of Health of New York State, described the publications of his Department. He said that there was a great call for the weekly *Health News* because it was made up of accounts of actual occurrences in the fields, and was therefore live news. The pamphlets published by the Division of Maternity, Infancy and Child Hygiene are also popular. Dr. Nicoll described the radio talks, and said that their widest circulation was not that transmitted over the radio itself, but was the newspaper publicity which followed the sending of copies of the talks to newspapers.

Dr. Nicoll said that health posters had not been of much value.

Mr. E. G. Routzahn, of the Russell Sage Foundation, described the essentials of health publicity writing.

Dr. Morris Fishbein, Editor of the *Journal of the American Medical Association*, described the extensive information system by which the A. M. A. can give accurate information regarding every doctor in the country from the beginning of his medical course down through his entire life. The A. M. A. has thousands of calls annually from newspapers and other sources, to

supply information regarding physicians and new cases.

Dr. Fishbein also gave much inside information regarding newspaper syndicates and their promotion of quacks, such as Coue and his trip to America.

Mrs. W. B. Meloney, Editor of the Sunday Magazine of the *New York Herald Tribune*, told of the changed attitude of newspapers toward health matters in recent years. While a few years ago it was the rule of some newspapers that the word "cancer" should not appear on the front page, now the newspapers carry whole columns of the proceedings of cancer conferences.

Newspapers also do much to correct misapprehensions of the public. A newspaper received hundreds of inquiries from women wishing to buy tape worms in order to reduce their weight.

Dr. Bundeson, Health Commissioner of Chicago, described the publicity of the Chicago Health Department. He said that he took his health writings home to his young daughter, and if she could not understand his article, he rewrote it until she did understand it.

He spoke of the appeal of health, and said that a big chewing gum manufacturer had got rich by advertising the digestive value of chewing gum after every meal.

Dr. J. A. Ferrell, of the International Health Board, gave a paper on the per capita expenditures for health in the several states. He placed Delaware at the head of the list with an expenditure of 329 cents per capita, and New York twelfth, with 116 cents. Dr. Nicoll said that the expenditure given by Dr. Ferrell was for only one half of the state, because none went to New York City. If that correction were made, New York would stand second in the list of states.

---

## OTSEGO COUNTY MEDICAL SOCIETY

The March meeting of the Otsego County Medical Society was held in the Oneonta Hotel this 8th day of March. Meeting called to order by Dr. F. H. Marx, President. Minutes of the December meeting read and approved. The following resolutions were presented and approved:

"The members of the Otsego County Medical Society at their regular meeting March 8th, desire to place upon its records the esteem and respect in which they hold the memory of Dr. William R. Seeber, for many years an honored member, and to express their deep sympathy to his family. It is further directed that these resolutions be published in the press and a copy be sent to his family."

"Whereas, in the death of Dr. George E. Merritt the community of Cherry Valley has lost a valuable practitioner, and The Otsego County Medical Society one of its oldest and most beloved members:

"Be it Resolved, That the Society voice this tribute to his memory by spreading this resolution on the minutes of the Society and sending a copy to his family."

E. J. PARISH,  
A. H. BISSELL, *Committee*

A request was made that Dr. A. H. Brownell prepare a history of the Society from June, 1906, to date. Dr. Boorn having at that time

given an exhaustive report of the Society and the same now on the minutes. This report to be submitted at the semi-annual meeting.

A committee was appointed to revise and publish the By-Laws of the Society.

It was decided that the September meeting should be a social gathering in the nature of a clam bake.

A revised and more uniform fee bill will be presented to the Society at the first meeting of the Lecture Series.

The Lectures given by the Board of Health

will be begun March 29th and continue each week for six weeks.

After the dinner Dr. Ralph Harloe of the Long Island College Hospital gave a most interesting and instructive illustrated address on the new method of treating empyema.

Members present. Drs. R. W. Ford, Otsego, E. C. Winsor, Schenevus, A. H. Bissell, Cooperstown, F. E. Bolt, Worcester, F. L. Winsor, Laurens, Dart, Parish, Latcher, Champlin, Marx, Lang, Mills, Getman and Brownell of Oneonta.

## KINGS COUNTY RESOLUTIONS

The Medical Society of the County of Kings at its meeting on December 21, 1926, appointed a committee of twenty-three members, of which Dr. Walter D. Ludlum was Chairman, to consider matters in which there was a difference of opinion between the county organization and the State Society. The committee appointed two subcommittees to consider the two questions of publicity in the *New York State Journal of Medicine* and Amendments to the Constitution and By-laws of the Medical Society of the State of New York. The subcommittees prepared two resolutions which were adopted by the whole committee, and were presented to the Medical Society of the County of Kings, at its regular meeting on February fifteenth.

The resolution in regard to publicity was as follows:

WHEREAS, the minutes of the Medical Society of the County of Kings show that the Medical Society of the State of New York, through its regularly authorized officials, has twice within a year refused to open the columns of its Journal to publish therein resolutions which had been regularly carried by the component Medical Society of the County of Kings, and,

WHEREAS, the membership of the Medical Society of the County of Kings feels aggrieved at this refusal to acquaint other component county societies of the alternative measure to the Webb-Loomis Medical Practice Act, and further, to its reasons for opposing the Webb-Loomis Act, and,

WHEREAS, the continuation of such an attitude would be prejudicial to the good feeling which must always exist between the Medical Society of the State of New York and the component county societies, be it

THEREFORE RESOLVED, that the Medical Society of the County of Kings hereby asks the Executive Committee of the Medical Society of the State of New York to direct that the columns of its Journal be always open for the publication of resolutions adopted by county societies when requested and that on moot matters affecting the welfare of all practicing physicians of the State of New York its columns be impartially open to opponents and proponents of pending legislation.

Concerning changes in the Constitution and By-laws, the committee reported

With regard to the amendments to the Constitution the situation is far less clear, except to the relatively

small number of members of this Society who have been delegates or actively associated with the meetings of the Medical Society of the State of New York. By the Constitution and By-laws of that body, the House of Delegates meet once a year and in the interim of its meetings the work of the Society is carried on by the Council. This Council when originally organized was small compared to its present membership and probably was, at least was intended to be, representative, having as a large part of its membership the councillors of the direct branches. With the passing of time and various amendments to the State Constitution and By-laws its membership has greatly increased. It consists of all the officers of the Society, which are a President, a President-Elect and two Vice-Presidents, a Speaker and a Vice-Speaker, five Trustees, a Secretary and Assistant Secretary, a Treasurer and Assistant Treasurer, the eight Councillors heretofore mentioned, and, besides these officers, the Chairmen of the Standing Committees, the Editor-in-Chief, and the retiring President for a term of one year after his term of office expires.

"The Council is obliged by the Constitution and By-laws to elect an Executive Committee which in the interim of meetings of the Council functions for the Council and therefore for the Medical Society of the State of New York. As matters have turned out the Council meets but a very few times, and for all practical purposes during the most of the year the Executive Committee of the Council is the Medical Society of the State of New York. In addition to this, certain members of the Council hold a more or less continuous office, whereas the other members come and go, these few somewhat permanent officers perfectly naturally dominate the policies of the Medical Society of the State of New York. The object of the amendments to the Constitution and By-laws herewith offered is to make the formation and continuance of such an oligarchy less easy and to restore the Council to a position of a more representative character and of greater influence.

"As you know amendments to the Constitution and By-laws presented at one meeting of the Medical Society of the State of New York must lie over until the next meeting of the Society one year later and be published in the meanwhile. If the resolutions about to be offered are adopted that is the course these proposals must take.

"ARTICLE I of the Constitution of the Medical Society of the State of New York says 'The purpose of this Society shall be to federate and bring into one compact organization the medical profession of the State of New York.'

"In order to accomplish this it is essential that the desires and opinion of the component parts of the Society shall be furnished with a mechanism of expression which shall function between the meeting of the House of Delegates, the present organization of the Council and

of the Executive Committee of the Council place upon the officers of the Society a responsibility for ascertaining and executing the wish of the Society with no proper means of learning its nature or detail. It is desirable that such means be provided and in order that this may be accomplished we propose the following amendments to the Constitution

"ARTICLE IV now reads —'The Council shall be composed of (a) officers of the Society, (b) Chairmen of the Standing Committees, (c) the Editor-in-Chief, (d) the retiring President for a term of one year after his term of office has expired' This to be amended to read

"The Council shall be composed of the President, the Secretary, the President-Elect, the Treasurer, and the President and Secretary of each of the District Branches'

"ARTICLE V now reads as follows —'The officers of the Society shall be a President, a President-Elect, two Vice-Presidents, a Speaker and a Vice-Speaker of the House of Delegates, a Secretary, an Assistant Secretary, a Treasurer, an Assistant Treasurer, five Trustees, and one Councillor from each District Branch, who shall be the President thereof. He shall be elected by the District Branch in which he resides for a term of two years. The officers, except the Councillors, shall be elected for one year or until their successors have been duly chosen. They shall take office at the termination of the annual meeting' This to be amended to read

"The officers of the Society shall be a President, a President-Elect, two Vice-Presidents, a Secretary and Assistant Secretary, a Treasurer and Assistant Treasurer, a Speaker and Vice-Speaker, five Trustees, and two Councillors from each District Branch, who shall be the President and Secretary thereof. They shall be elected by the District Branch in which they reside, for a term of two years. The officers, except the Councillors, shall be elected for one year or until their successors have been duly chosen. They shall take office at the termination of the annual meeting'

"SECTION 26 of the By-laws to be repealed and the following substituted

"The Executive Committee of the Council shall be constituted as follows. The President, the Secretary, the Treasurer, and four of the eight Presidents of the District Branches, 1, 3, 5, 7, serving for one year and those from District Branches 2, 4, 6, 8, the next. The Executive Committee shall, when elected, organize immediately and elect a Chairman, a Vice-Chairman and a Secretary. The Executive Committee shall hold regular meetings at times and in places that shall be fixed by the Chairman and at other times subject to the call of the Chairman, and any two members of the Executive Committee may require the Chairman thereof to call a meeting for such time and place as shall be designated by them in writing, of which the members shall have at least three days' notice. Four members shall constitute a quorum. It shall prepare a budget to be acted upon by the Board of Trustees'

"SECTION 38 of the By-laws to be amended to read

"The Speaker shall preside at all meetings of the House of Delegates and shall perform such other duties as parliamentary usage may require.'

"SECTION 62 of the By-laws to be amended to read

"The President shall report to the Council the committees that he shall deem expedient for the purposes of the meeting of the House of Delegates and the members of these committees shall be elected by the Council at the meeting of that body in February preceding the meeting of the House of Delegates'

"SECTION 20 of the By-laws to read

"It shall meet once during the months of October, December, February and April of each year, the time and place to be selected by the President, and it shall meet at other times upon the request in writing of five members of the Council upon the call of the President'

The Medical Society of the County of Kings adopted the report of the Committee and directed that copies be sent to all the county societies of New York State

## THE NEW YORK TUBERCULOSIS AND HEALTH CONFERENCE

The New York Tuberculosis and Health Conference held a two-day session on January 19 and 20 in the Hotel Biltmore, New York City. The Conference was under the auspices of eight health organizations, as follows

The United States Public Health Service  
The New York State Department of Health  
The New York City Department of Health  
The Medical Society of the State of New York.

The State Charities Aid Association  
The New York City Tuberculosis and Health Association.

The Milbank Memorial Fund  
The Bellevue Yorkville Health Council

Those sponsoring the Conference therefore included the entire trinity of public health organizations — physicians, departments of health, and lay organizations. The discussions were carried

on from the standpoint of each group of organizations

The control of tuberculosis was the principal subject discussed, but the subject of diphtheria, child welfare, and school health work were also on the program. These subjects were treated by experts who are well known throughout the Nation. Three sessions were held on each of the days, and the luncheon hour was utilized for some of the most interesting of the addresses.

It is impossible for this JOURNAL to record all the addresses and discussions, or even to report all those which have a medical bearing. Four addresses have therefore been chosen because the speakers, Dr. Allen K. Krause, Dr. Lawrason Brown, Dr. E. R. Baldwin, and Dr. David R. Lyman discussed medical points which are of direct interest to every physician who practices medicine in New York State. These addresses are printed on pages 391 to 402 of this JOURNAL.

## THE VICTOR IN EVOLUTION

The restricted department called "More Truth Than Poetry," conducted in the New York *Herald Tribune* by James L. Montague, is always truthful, and its author clothes dry scientific facts in interesting language with rhyme and rhythm. It would seem that the following poem from the *Herald Tribune* of March 23 sets forth evolution in a way that would meet with universal approval, even in Tennessee.

"I do not wonder, little bug  
Upon yon cocklebur,  
That you regard me with a smug  
And arrogant hauteur,  
Your attitude of chill disdain,  
Your grim, unsmiling face—  
Though supercilious and vain—  
Denote a conquering race.

"Thus man, no doubt, back in the days  
Of dim and dusty yore,  
Regarded with a cold, stern gaze  
The giant dinosaur—

Which brute, despite his size and strength,  
And all his mighty kind  
Were driven from the earth at length—  
While man remained behind,

"Remained behind, and brought to heel  
The jungle's strong and great.  
He bade the titan Jumbo kneel  
To bear his puny weight,  
And banished to their distant lairs  
In forest or morass,  
The lions, hippopotami and bears,  
Which soon, in turn, shall pass

"So, bug, no wonder that you leer  
So gloatingly at me,  
For men shall shortly disappear,  
The while the ant, the bee,  
The jigger and the mite shall whizz  
And flutter æons long,  
For evolution's battle is  
Not ever to the strong"

## TEA DRINKING IN TUNIS

The newspapers of March 31 carried a story of the evil effects of tea drinking on the inhabitants of Tunis told by a Tunisian doctor who was lecturing in Paris. Tea was introduced into Tunis during the World War, and now the annual consumption averages over one pound per person. The New York *Times*, discussing the report editorially, says

"The victims gather around a teapot at the cocktail hour and keep the kettle boiling all night long. No sleep and no dinner for them as long as the tea holds out. They go home in the morning in a state described as general debility."

The editorial writer is at a loss to explain the evil effects of the tea. "Many other people having free access to bountiful supplies of tea do

not get drunk on it. They can take it or leave it alone. Either the tea of Tunis is a special brand with something in it, or the inhabitants are peculiarly susceptible to the drug in the beverage."

It would not seem to be necessary to ascribe the bad effects of the tea to the tea itself, or to a drug added to it, or to a peculiar sensitiveness of the people to tea. A fad of social tea drinking seems to have arisen suddenly, and to have taken such a hold on the Tunisians that they sit at tea parties all night long. Probably if the report of the Tunis doctor were at hand, it would ascribe the general debility to the exhaustion following all-night parties, rather than to an extraordinary effect of the tea itself.

## TOOLS TO CATCH MURDERERS

A doctor is one of the first persons to be called after a murder and on his actions rests much of the responsibility for the discovery and presentation of legal evidence regarding the murderer. What tools form the standard equipment in the investigation of a murder? Doctors will be interested in the answer given in the New York *Times* of March 22.

"Arthur Woods tells in his book how the tools used by the New York police in murder cases are kept packed in a bag, ready at all times to

be taken to the scene of the crime. Here is the list

Fingerprint outfit	Paper
Searchlight	Envelope
Steel tape measure	Twine
Sealing wax	Tags
Small box of tools	Saw
Screwdriver	File
Stenographer's notebook	Pincers
Rubber gloves	Scissors
Bottle of antiseptic wash	Jimmy
Soap and towel	

"A stenographer and a photographer are likewise always on duty to accompany the detectives"

## PANICS

Unreasoning fear seizing upon a mass of humanity is seen at its worst in a theatre. When a fire breaks out, for example, the fear of being unable to escape leads everybody to rush for the exits at once and to crowd into a few seconds' actions which could be done safely in five minutes, for it is hardly likely that any calamity, much less a fire, could overwhelm an audience within five minutes. Fortunately New York City people are accustomed to being pushed and crowded and jammed twice daily on the subways, and so they are somewhat immunized against panics in theatres.

The teachers in public schools of New York state are required to train their pupils to leave the building in a rapid, orderly way in case of a fire. It is entirely reasonable to require the managers of theatres to train their actors and attendants to manage an audience that is threatened with panic.

The New York *Times* of March 16 describes the effective means adopted by the Gayety Bur-

lesque Theatre of Brooklyn to avert a panic in its audience, and used the following headlines: "Wise-cracks calm audience in fire 1200 viewing Gayety Burlesque in Brooklyn orderly as flames start in gallery Go out choking, chuckling Property man and actor get into action as women show signs of fright Damage is slight."

When some women in the audience showed signs of fright (just as probably they were men) "Dick Foster, the property man, a plump-faced person in shirt sleeves, with a cap cocked on one side of his head, walked out before the curtain and 'wise-cracked' them back to calmness.

"Take your time," he shouted, smiling amiably. "We're here and we're not worrying. Save your seat checks. This is only a rainy day. Rain checks will be issued by the firemen out in front." Then, turning to Gilmore, he said in a loud aside, "Brother, our show's so hot it set the theatre afire."

"The audience thought this an excellent joke and strolled out choking and chuckling."

---

## BIRTH RATES

Declining birth rates and stationary number of population are subjects of frequent discussions and various interpretations. The New York *Times* of March 12 discusses these topics in an editorial, basing its facts on an interview with Professor W. S. Thompson of the Scripps Foundation. It says: "Contrary to the general impression, the birth rate in this country is higher than in the European countries." The editorial points out that the professor means "some" European countries, especially France, England and Germany. The editorial continues:

"Professor Thompson is right in assuming that on the subject of population increase many erroneous impressions are afloat. The most celebrated instance is that of the alleged phenomenally low French birth rate. But of recent years the truth has spread that France's stationary population is not due to too few births, but to altogether too many infant deaths.

"We have popular fallacies at home. There is the standard complaint that old-stock Americans are refusing the responsibilities of parentage, and

so in the course of the years are bound to be swamped by the prolific immigrant stock. But while it is true that the birth rate among native Americans of long descent is lower than among immigrants, there is evidence to show that the native-born children of immigrants have a lower marriage rate and birth rate than the 'old' Americans. This is explained by the sharp swerve away from European standards which is observed among the children of immigrants in so many spheres of the individual and social life. This consideration was presumably in Professor Thompson's mind."

Large families in the past have usually been associated with a high infant mortality rate, of which one indication is a row of small headstones in the family burying grounds of a century ago. One striking example was that of the graves of a well-to-do father and mother at the end of a row of five small stones of their children aged from two to eight years. The modern ideal is healthier, rather than more, children.

---

## THE PENALTY OF RENEWED YOUTH

The New York *Herald Tribune* of February 26 has the following news item which sets forth a new complication of a Voronoff operation:

"A dispatch from Budapest to *Le Soir* says that a large Hungarian insurance company has ceased to pay life-time annuities to a prom-

inent client on the ground that he broke the contract by submitting to a Voronoff monkey gland operation.

"The company charged that this was an indication of bad faith, releasing it from every obligation. The case will be decided in court."

# OUR NEIGHBORS

## PUBLIC RELATIONS COMMITTEE OF THE MAINE MEDICAL ASSOCIATION

The appointment of a public relations committee by the Medical Society of the State of New York was anticipated by the appointment of a similar committee by the Maine Medical Association, whose *Journal* for March records the minutes of a recent meeting of the committee. The committee discussed medical bills rendered to insurance companies, and immunizations against diphtheria, and advocated that the choice of physicians to conduct public clinics should be with the county medical societies. The committee also adopted a detailed set of rules under which public health nurses should deal with the people in medical problems.

The same issue of the *Journal* discusses the discharge of civic duties by doctors in an editorial from which the following quotations are taken:

"Maine was the first state in the Union to bring about a definite alignment in which the organized medical profession, as represented by the state medical society, is brought into actual working connection with the volunteer health forces, as represented in Maine by the Maine Public Health Association, and the official agency represented by the State Department of Health."

"Maine physicians are coming to realize the

important fact that the medical policies of the Maine Public Health Association are sanely and constructively supervised by our State Medical Association Committee. Furthermore, the medical profession is well represented on the Executive Committee of the Public Health Association.

"The State Health Commissioner is a member of the Maine Medical Association's Committee on Public Relations, and this committee also includes medical members of the Public Health Association's Executive Committee."

"With the development of better and better team work between the three major groups interested in health work—the State Department of Health, charged with the enforcement of health laws and ordinances, the operation of state laboratories, the compilation of vital statistics, etc., the scientific group, as represented by the Maine Medical Association, and the volunteer or lay group engaged in educational, organization and health promotion activities, as represented by the Maine Public Health Association—Maine is being cited as a leader by forward-thinking medical men, by health educators and health administrators throughout the United States."

## HOW TO MAKE A PERIODIC HEALTH EXAMINATION

The March number of the *Journal of the Iowa State Medical Society* reports a demonstration of how to make a periodic health examination, given by Dr. C. A. Elliott, Professor of internal medicine in the Northwestern University Medical School, Chicago, before the Iowa State Medical Society on May 13, 1926. The patient was a physician who submitted to an examination whose results are reported as follows:

"This applicant, one of your own members who has consented to present himself for such an examination, has filled out the blank that has been proposed. There is nothing of particular interest here. 'Age forty, a physician, conditions of work are satisfactory.' We as physicians should recognize the fact that a great deal can be done towards adapting the lives of people toward less exacting conditions. Ofttimes it is a simple thing to do, a matter of a change of occupation, exercise, etc. There has been no serious illness in the history of this case. He gets a moderate amount of exercise. His weight is 139 pounds, and it is stated here that his usual weight is 145 pounds,

so that there has been an apparent loss of weight. This is a matter which should receive your attention. His height is five feet ten inches, weight 139, and on consulting the table here one finds that his weight should be in the neighborhood of 160 pounds. Therefore he is definitely underweight, perhaps 15 pounds. Blood-pressure, 117, d 84."

"In the privacy of your own office this examination should be made with the applicant stripped. There are many points that go unobserved under other conditions, for instance, hernia, flatfoot, or a poor attitude in standing. It would be my desire to have an examining table, there should be charts, scales and blood-pressure apparatus. You should have perhaps nose and throat instruments in order that you may look in the throat, but on the whole the apparatus that is needed is simply that which each general practitioner has in his own office."

"We note in this case that the subject is tall and rather thin, that his hands are cold and

(Continued on page 440—Adv. xiv)

## The Management of an Infant's Diet

## Mellin's Food—A Milk Modifier

## Constipation

It is common observance among physicians who use Mellin's Food as a modifier of milk for infant feeding that their baby patients are seldom troubled with constipation, and if this annoying symptom does occasionally appear it is easily corrected by increasing the amount of Mellin's Food in the daily mixture or by some other slight readjustment of the formula

Some fault in the arrangement of the food formula is practically always the cause of constipation, so it seems logical to overcome the difficulty by rearranging the food elements to a more perfect balance rather than to employ medical means, which at best afford temporary relief only

In a pamphlet entitled, "Constipation in Infancy", the common causes of constipation are set forth for the physician's consideration, also practical suggestions for their correction. All of the matter presented is based upon observation extending over a long period and will prove of good service to every physician interested in the subject

A copy of the pamphlet will be sent promptly upon request. Samples of Mellin's Food also if desired

Mellin's Food Co., 177 State Street Boston, Mass.

(Continued from page 438)

clammy I think the doctor is perhaps more excited than I am at being here, if not, something is driving him to some vasomotor change as represented by cold, clammy, sweaty hands, a situation we see so frequently among people we recognize as having an effort syndrome. His general appearance is quite normal. A definite goiter is present, there is a mass that is quite large on the right side, he states that he has noted there has been some enlargement present for six years.

"In these examinations one should, of course, search for possible sources of infection. We note that his throat is quite normal, that the tonsils are definitely present and seem quite normal. In the case of the teeth, there is a possible source of infection there which should be excluded by proper X-ray examination. One feels that the cervical glands are just palpable, the axillary glands are palpable.

"Without going into great detail, but reviewing the findings in a suggestive way, here is a man who gives us a lead. Here is one point we pick up on examination. Although he complains of nothing, being a healthy individual carrying on his occupation, yet we see that he has a goiter, we see that he has much filling in the teeth, we see that his hands are clammy, cold, sweaty. Therefore we go ahead with those findings in mind and search for a possible cause of these manifestations. In examining the heart, its left border is best determined by palpation, and we are very much interested, in view of what has been found here, in accurately determining the position of the apex beat. On palpation we can feel that it is well within the normal range. On auscultation one hears normal heart tones. The blood-pressure is low, as has been indicated.

"A general examination of this kind should be conducted to the final conclusion. The lungs and abdomen should be gone over carefully, the reflexes should be noted. It is an excellent thing to give such patients a functional heart test, the hopping test is as good as any, and certainly far better than any mechanical contrivance that we know of in giving us an accurate idea of cardiac efficiency.

"After such an examination as that, our findings should be written up, the positive findings only to be written on the blank. Here are the things we note in this subject. He has an adenomatous goiter, his teeth are possibly a source of infection, he has lost weight. We note that he shows some vasomotor disturbances as though he was to some extent being driven. Then the obvious thing to do is to suggest that something be done about it, that as a matter of record if for no other reason the metabolic rate should be taken, X-rays of the teeth are in order,

(Continued on page 441—Adv xv)

possibly it might be well to have a good nose and throat man go over him to be sure to eliminate infection in that regard. In such a case as this you would debate the advisability of some treatment. Here is a man, presumably healthy, he has no complaint. You find that he has disability to some extent, and if there is anything to be done about it you ought to see that he is put on the right road, and if nothing can be done about it a record at least should be kept for future reference."

### POLYCYTHEMIA

Polycythemia or Vaquez's disease, is the subject of a paper in the March *Journal* of the Missouri State Medical Association, by Dr. Oliver Abel, Jr., of St. Louis, from which the following abstracts are taken.

"The condition is characterized by polycythemia, an increased blood volume and a large spleen, the etiology of which is unknown. The treatment at present offers nothing in view of a permanent cure, although roentgen ray, radium, benzol and phenylhydrazin hydrochloride have given temporary relief in some cases.

"Four of the cases that we are to present were treated with phenylhydrazin hydrochloride. Phenylhydrazin was first used to produce secondary anemia in animals, after which Eppinger suggested its use in the treatment of polycythemia vera.

"Brown and Giffin report seven cases treated with phenylhydrazin in which the clinical improvement was satisfactory in all but one case, in the latter marked hypertension persisted. A gradual increase in the red blood cells and volume of blood necessitated a second course of treatment in from three to six months after the first. The drug was given in doses of 0.1 gms three times a day, the total given varied from 3.4 gms to 7.6 gms. It was found wise to discontinue the use of the drug when the red blood cells dropped to 4,500,000, it is estimated the destruction of blood will continue for approximately a week longer. They state that phenylhydrazin causes a more consistent improvement in the symptoms and a more constant reduction in the blood volume than either radiotherapy or venesection.

"Our results following the administration of phenylhydrazin were rather disappointing. It is possible to produce a reduction in the number of red blood cells and in the percentage of hemoglobin. However, it is difficult to regulate the dosage. In two of our cases severe anemia was produced. The patient as a rule feels better when not taking the drug. Its effect is only temporary in character and it certainly cannot

## How Sanborn Metabolism Apparatus Will Help You

YOU can accurately diagnose many ordinarily perplexing cases with Sanborn Metabolism Apparatus. You can identify the important thyroid disorders, study and treat more intelligently many special cases in diagnosis, therapy and surgery.

Your patients will be gratified by this exceptional service.

### Metabolism Testing Aids Success

Why rely upon outside tests? You or your assistant can test metabolism quickly, easily and accurately in your own office with the

### SANBORN GRAFIC METABOLISM TESTER

\$165.

THE Sanborn Graphic is simple, compact, durable—scientifically precise. It automatically records every detail of the test on a chart ready for filing. Saves you the nuisance of laboriously taking down results.

You can make the test and get the basal metabolic rate in less than 15 minutes without any complicated figuring. Any one can easily operate the Graphic. It's portable, and costs under 20 cents a test to run.

Hundreds of eminent physicians—names on request—heartily endorse the Sanborn Graphic. It is well worth your while to learn more about it.

## SALIPYRIN *Riedel*

Is a chemical combination of antipyrin and salicylic acid. The therapeutic effects of both these components are preserved, although modified by close chemical union and in a very great degree deprived of the dangers of mechanical mixtures.

Salipyrin is distinguished from other salicylates

by the comparative freedom from ill-effects (absence of free antipyrin) and prompt antipyretic and sedative action.

**INDICATIONS** Influenza, Colds, Catarrh of the Nose and Throat, Rheumatism, Neuralgia, Alcoholic Excess, Pleurisy, Dysmenorrhea, Metrorrhagia, Vaginitis, etc. If given early in the attack, Salipyrin generally succeeds in aborting colds.

Salipyrin is supplied in powder form and as SALIPYRETS in tablets of 7½ to 15 grains each.

Approved by the Council on Pharmacy and Chemistry of the American Medical Association for inclusion with N. N. R.

**RIEDEL & CO., Inc.**

Berry and South 5th Streets, Brooklyn, N. Y.

(Continued from page 441)

be expected to influence the course of the disease. As pointed out by Giffin, the damage to the vascular system in polycythemia is constant and progressive in character. The association of duodenal ulcer and polycythemia vera in two of our cases may be considered coincidental in character. However, the disturbance in the blood circulation in the duodenum might possibly be an etiological factor in the production of ulcer.

"Wm J Mayo removed the spleen in one case of polycythemia vera. The case was apparently in its terminal stages and the operation was performed because of the frequent severe hemorrhages. The patient made a remarkable recovery and has remained well for four and one half years following the operation.

"The part that the spleen plays in the etiology of polycythemia vera is not known. However, when we consider the progressive character and the eventually fatal outcome of the disease it would appear logical that splenectomy should be given a trial in a series of cases."

## EARLY DIAGNOSIS OF CANCER OF THE STOMACH

The February issue of the *Ohio State Medical Journal* contains an article on the early diagnosis of cancer of the stomach by Dr. Jonathan Forman, of Columbus. The article is interesting because of its arrangement in the form of five rules, with brief comments—*Editor's note*.

*"Rule I Every patient past middle life who having never had any stomach trouble whatever suddenly develops a dyspepsia should at once be considered a case of gastric cancer until proved otherwise."*

"One of the first symptoms of this are acid eructations coming on some little time after the meal. Sour eructations in late adult life should never be ascribed to hyperacidity until definitely proved so by direct investigation. Then there develops an epigastric discomfort after meals. The appetite is diminished early and especially is there developed a distaste for meats. The practical thing here is not whether cancers develop from gastric ulcers but the fact that from 80 to 90 per cent of gastric cancers have been found to arise de novo in healthy persons.

*"Rule II Every patient past middle life who develops a sudden loss of strength for no apparent reason, or because of a slight gastro-enteric disturbance, should be considered a case of gastric cancer until proved otherwise, especially if there follows a progressive anemia without other cause."*

"Given dyspepsia in a heretofore well person with asthenia and developing anemia we should become very suspicious of gastric carcinoma, and

(Continued on page 443—adv. xvii)

(Continued from page 442)

we should proceed to use the stomach tube at once

*"Rule III The stools of every suspected patient should be examined for occult blood"*

"This is a simple inexpensive test which requires but little time and may prove of great value. If positive, it is ominous, provided of course that there is no bleeding in mouth or rectum. As a rule, the bleeding of cancer of the stomach is relatively small in amount but persistent and unaffected by rest and non-irritating diet. The bleeding of ulcer is more marked but usually disappears under appropriate treatment

*"Rule IV Every patient in whom is demonstrated the absence of free hydrochloric acid and the presence of a definite amount of lactic acid in the test meal is a case of gastric cancer"*

"The technique of the use of the stomach tube is simple. The small tubes now employed are not objectionable to the patient. I, personally, have never seen a case of gastric cancer in which there was not an absence of hydrochloric acid and the presence of an appreciable amount of lactic acid in the test meal

*"Rule V Every patient in whom there is a suspicion of gastric cancer should be X-rayed but very little weight should be attached in these cases to a negative report"*

"Most of the criteria, upon which an X-ray diagnosis of gastric cancer is made are late manifestations and are therefore not going to help us much in the early recognition of the trouble. It so often furnishes corroborative evidence of worth that it should be employed in all cases of this kind. It is also of value in localizing and in ruling in-or-out the presence of pathology in the adjacent viscera

"When the history and other clinical facts agree, a presumptive diagnosis is to be made and an immediate exploratory laparotomy urged. This advice is to be given even though the roentgenologic report is negative"

Summary We have presented dogmatically the available data presented early by more than 85 per cent of patients with gastric cancer. The use of these facts will make it possible to get a much more respectable percentage of patients to the surgeon in such a stage that something more satisfactory can be offered than the usual palliative gastro-enterostomy"

# OSCODAL

## Palatable Cod Liver Oil Therapy in Tablet Form

OSCODAL is a palatable cod liver oil concentrate containing the essential principles of the oil—the fat-soluble vitamins—with the following advantages.

- (1) Elimination of objectionable bulk, nauseating odor and unpleasant taste.
- (2) Accurate dosage
- (3) Every lot is physiologically standardized.
- (4) Oscodal is readily taken
- (5) Oscodal is acceptable at all seasons

OSCODAL is marketed in bottles of 100 tablets  
Literature on request.

## JUSTIFIABLE ABORTION

The *London Lancet* for January 20, contains an article by Lord Reddell on the ethical, legal and medical aspects of abortion, one paragraph discusses a phase of the problem from a standpoint which will be especially interesting to all general practitioners

The paragraph gives a brief description of four cases, and then asks the question "What should the practitioner do under such circumstances?" The author answers the question as follows

"We know, of course, that he should invariably get the benefit of a second opinion, and we know that in modern practice it is usual to secure such an opinion from a specialist in the disease affecting the pregnancy It is for the specialist to say whether the woman can safely be allowed to go to full time Consequently in the four typical cases quoted, it would seem to be the duty of the doctor to call in a general physician or a

mental specialist, as may be most appropriate If he advises in writing that the continuation of the pregnancy is likely to kill the woman, ruin her health, or drive her into a mental home, then in my opinion, *quantum valeat*, as the lawyers say, the procuring of a miscarriage is not only justifiable but a duty Cases in which the patient misrepresents or exaggerates her condition with the object of persuading the doctor to terminate the pregnancy are not uncommon Therefore extreme care is necessary when making a diagnosis

"It would be futile to disregard the fact that some practitioners are ready to seize on any medical or surgical reason to justify an abortion when desired by the patient to avoid an unwanted child It is useless to discuss such conduct The offence cannot readily be detected in the case of a married woman attended by two medi-

cal men Nevertheless it is a risky game When required to deal with a pregnant unmarried woman, the practitioner is faced with problems of exceptional difficulty and danger If he procures an abortion his motives are open to question, and if he fails to do what is necessary to preserve the life or health of his patient he is liable to grave moral condemnation and may possibly incur serious legal consequences When faced with such a problem, the practitioner should always remember that secrecy is the badge of fraud If he acts openly, and if he is supported by another sound opinion, he has little to fear if his motives are right It is not a crime for an unmarried woman to become pregnant, and her medical adviser has no right to condemn her to death or to serious morbidity because she happens to be unmarried"

## BONE CYSTS IN CHILDREN

Diseases of bones are receiving more and more consideration, and are recognized by general practitioners with increasing frequency. *The Long Island Medical Journal* for March contains the following concise article on the subject from the pen of Dr. Harold K. Bell of Brooklyn.

This article and the one on cleft palate reprinted on page 447 were two numbers of the program of the Associated Physicians of Long Island that were described in an editorial on page 190 of the February 15 issue of this JOURNAL. The program was unique in that eighteen papers were presented within ninety minutes, as the result of careful preparation and planning.—EDITOR'S note

"The pathogenesis underlying the production of bone cysts is still a debatable question, though the majority of pathologists are now agreed that is a low grade type of chronic inflammation termed *ostertis fibrosa* or fibrous *ostertis*. Of 89 cases collected by Bloodgood, 69 were considered definitely related to fibrous *ostertis*.

"Bone cysts occur usually in the medullary canal of long bones, particularly the humerus, femur and tibia, and seldom are found in short or flat bones. A bone cyst enlarges slowly, and as it grows it expands the shaft of the bone and encroaches upon and thins out the cortex, meanwhile replacing the medullar substance with connective tissue.

"Bone cysts occur particularly in children and frequently produce no symptoms. Subjective symptoms are so rare the condition is generally unrecognized until fracture occurs. With the expansion of the cyst, the cortex is thinned out to tissue-paper thickness, often permitting a very slight injury to produce the fracture. So trivial a force produces this pathological fracture and the accompanying symptoms are so mild, that fracture of the bone is often not suspected. X-ray makes the diag-

nosis definite. The shaft of the bone is enlarged, the cortex thinned, the medulla, instead of showing a relatively dark shadow, is exceedingly clear and often shows trabeculae in the wall of the cyst. The line of fracture shows distinctly.

"But X-ray interpretation is not entirely free from error. For a somewhat similar picture may be presented by many other medullary growths possessed of a bony capsule and producing osseous absorption. Many bone cysts are produced as the result of softening of solid neoplasms such as myeloma, giant-cell sarcoma, chondroma, myxoma, etc. Cysts form occasionally from softening in *ostertis deformans* and in *osteomalacia*.

"But the age of the patient divides medullary (or central) tumors into benign or malignant. Bloodgood says that if the patient is under 15 years of age and the central tumor is in the shaft, one may be quite certain it is a bone cyst. The myeloma is very unusual in children, and myeloma is generally multiple.

"In the matter of treatment, bone cysts frequently heal spontaneously, and, after fracture, healing and ossification are often rapid. Operative treatment is not to be considered in such cases. But if healing of the fracture and ossification of the rarified bone do not ensue, open operation is indicated. This consists of incision and thorough curettement of the cyst contents and its connective tissue lining, and replacement within the osseous cavity of bone-chips or a transplant, and closure without drainage. The case is further treated as a simple fracture, needless to say, union is usually much slower than in the ordinary fracture."

## HARE LIP AND CLEFT PALATE

What to do in hare lip and cleft palate is told in the following article by Dr. Roger Durham of Brooklyn, published in the March issue of the *Long Island Medical Journal*—EDITOR'S note

"Hare lip represents a failure in fusion of the lip, and there may result a unilateral or a bilateral hare lip, an incomplete union involving only part of the lip, or a complete failure with the hiatus extending into the nares. The extent of failure of union of the maxillary processes, or of the hard or soft palate, results in a degree of separation of the anterior portion of the jaw, varying in different babies, or in an hiatus of the soft or hard palate. There may be present merely a notch at the alveolar border that represents the slightest degree of failure of fusion, or on the other hand, extreme degrees of separation of the hard or soft parts may appear that are impossible of repair.

"The condition is recognized at birth and the question that immediately arises is what is to be done to cure the deformity, and when is the time to do it. The parents must be informed of the serious nature of the operative relief, of the technical difficulties of the various steps, and of the likelihood of not obtaining complete success at each operation, because of infection, poor healing qualities of a none too vigorous child, and the location of the field of operation. The cure is to be secured only by a series of operations conducted over a period of months, and the number of steps will depend upon the success or failure of the preceding step and the time chosen for the steps must be determined in part by the health and condition of the little patient.

"For the average fairly normal healthy child the technique and successive steps are those recommended by Thompson (James E. Thompson, Galveston, Texas) and adapted to my own experience.

### Irrigation and Drainage in NASAL THERAPY

COPYRIGHTED

The above is a 16-page booklet we recently had prepared on this subject. It is a remarkably comprehensive treatise on the subject of nasal irrigation. With it is furnished a large chart showing 30 indications with their etiology, pathology, symptoms, diagnosis, prognosis and treatment.

This booklet was compiled primarily to help the doctor in successfully prescribing

**NICHOLS  
NASAL SYPHON**

but it can be of use to every doctor. The chart should be kept for reference.

A copy will be mailed to any doctor for the asking. Write today!

**NICHOLS  
NASAL SYPHON**  
Incorporated  
159 East 34th Street  
New York City

"First. At two weeks repair the superior nares processes.

"Second. At the same time repair the lip if the condition of the child permits. If the child can not stand the added operation at the time, operate upon the hare lip as soon as possible after recovery from the first operation.

"Third. Repair the hard palate by the eighth month or before the sixteenth month.

"Four. Repair the soft palate six or eight weeks after the operation on the hard palate, or if possible by the eighteenth month.

"The cleft palate interferes with the proper nutrition of the child because of the mechanical impossibilities of nursing at the breast, and the difficulty of swallowing, and the frequent regurgitation of food, and the resulting malnutrition. Therefore, the closure should be done early.

"The superior maxillae are soft, pliable, and easily moulded at two weeks, and the dangers of the operation are less than later in life, therefore, operate early.

"The repair of the lip helps approximate and mould the upper jaw after suture, and it also saves the distracted parents the embarrassment and need of apologies consequent upon this horrible deformity. Therefore, operate early.

"The repair of the palate should be completed by the time the infant is learning to speak, so that the speech may be more nearly perfect. This operation is usually done in two steps. When done at one sitting there is risk of non-union of the whole, whereas even a small degree of union of the hard palate makes the chance of success easier when the soft palate is attempted."

# NEW YORK STATE JOURNAL of MEDICINE

PUBLISHED BY THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

VOL 27, No 9

NEW YORK, N Y

May 1, 1927

## THE OFFICIAL YEAR

THE publication of the annual reports of the officers and committees of the Medical Society of the State of New York in this issue affords the occasion for editorial remarks on the progress of the Society during the official year which began at the annual meeting of 1926

Progress is measured by means of ideal standards of perfection which cease to be ideals as soon as they are attained. The best progress is made when the immediate objectives are not too far beyond easy grasp. Progress is the most sure and enduring when it is a growth, symmetrical and solid, unfolding from a pre-existing germ.

The ideals and standards of the Medical Society of the State of New York have undergone surprisingly few changes during the past quarter century. They have been stated over and over again by wise medical leaders as those who have read the "Looking Backward" editorials in this Journal may have discovered. Indeed one observer who has delved into the printed records of the Society has said that the same suggestions for improvements in the activities of the society are repeated every five years. Now this does not mean that the Society has failed in its activities. It means rather that diagnoses regarding the health and vigor of the medical profession have always been correct and that the leaders have always been in agreement regarding the fundamental treatments and management of the conditions. The responses to the suggestions of the medical leaders have not been waves of enthusiasm, which have curled in spectacular breakers upon the shore of progress and receded again in a wasteful undertow. They have rather been a rising tide which has covered the dull flats of ignorance and complacency with shining inspiration and activity.

The very nature of the membership of the Medical Society of the State of New York does not allow progress to be sudden and spectacular. The Society is composed of ten thousand doctors whose training and daily work make them individualistic, yet ethical and progressive beyond the standards of any other profession. They are grouped in county societies,

and these in turn constitute the State Society. The essence of the State Society lies not in itself, but in the county societies and their individual members. New activities must represent the desires of the great body of individual members. Progress in the State Society therefore depends upon the education of the individual doctors rather than upon the announcement of new plans by a few officers. The reiteration of the same ideals and plans by the leaders year after year has produced a steady growth in the lusty body of the medical profession which is ages old and yet is endowed with perennial youth. Medical leaders may come and go, and the tenure of office is measured by single years, but the great body of the medical profession changes its identity only once in a generation, for the majority of its members practice their calling over a quarter century or more.

The great item of medical progress of the Medical Society of the State of New York during the past year has been the development of practical means by which the medical profession may discharge its duty to the community in distinction from the individual patient. It has taken concrete form in ways and means of practicing civic medicine in distinction from private practice. Far-seeing leaders have for years been reminding family physicians of their broader duty to the community, and of the necessity that they engage in public health work, or else see the rise of a new group of endowed or salaried physicians who would displace the family doctors in the estimation of the public. Physicians in private practice have always been conscientious in meeting their civic duties, which at first were almost purely charitable, but are now largely humanitarian. Physicians have been jealous of their prerogatives as qualified healers of the sick, and of their duty to justify the trust of the people in their medical skill and their willingness to apply it to all the suffering. The difficulty in the way of providing that service has been the impossibility that those who lacked the financial and mental means could carry out the advice of the doctors. Physi-

cians have always been willing to give their medical services freely, but they could not be expected to spend hours in persuading people to live hygienic lives, to submit to corrective operations for conditions which were not at once disabling, and in general to make use of advice for which they saw no immediate need. The unwillingness of physicians to play the part of the economist, the public official, and the social worker, led many leaders in those fields to assert that doctors were not interested in preventive medicine, and to threaten to create a new class of medical men who would engage in that line of practice exclusively. The reply of the physicians has always been that they were willing and anxious to supply the medical services and advice to all who needed it, if the other groups of the community—the financiers, the office holders and the philanthropists—would provide the extra-medical services which were also essential. The past decade or two has seen the rise of hospitals, public health nursing organizations, child welfare societies, and other health organizations, all of which depended primarily on the practice of medicine by qualified physicians. The development of practical means of coordinating all these agencies—professional, official and philanthropic—has been of slow growth. Henry James speaking of art has said that it takes a long history to make a tradition, a long tradition to create a taste, and a long taste to make art. This statement is equally true in the development of public health service and preventive medicine. Doctors on the one hand, and community workers on the other, have carried on attempts at tentative solutions of the problems with varying degrees of cooperation and success, until in the course of a decade or two their aspirations, their partial success, and their failures developed into understanding of the practical methods of work and of the recognition of the peculiar fields of activities of the various groups.

The outstanding original accomplishments of the Medical Society of the State of New York, during the past year or two has been the recognition of practical means and methods by which all health organizations can work together without intruding upon one another's peculiar fields. Those who attended the District Branch meetings last fall were impressed by the reports of the practice of public health and civic medicine by a sufficient number of county medical societies to assure the success of the newer methods of the practice of preventive medicine. The final step in the promotion of this practice has been the formation of the committee on Public Relations which is coordinating the activities of all the various agencies to the satisfaction of all the groups—the public, the physicians and the non-medical organizations—with physicians as the leaders

and authoritative advisors. This committee is beginning a work whose result in preventive medicine will be similar to that in the field of hospital establishment and administration, in which a happy coordination between all groups has been recognized for a decade. The happy birth of the new methods in preventive medicine has been accomplished only after a long period of pain and travail, which now seems to be at an end. The ripening of fruits of the oft-repeated efforts of leaders in the medical societies in the State has been possible only within the last year or two. But at the present time the medical profession of New York State may properly claim the honor of being the first to present a practical solution of the problem of the practice of preventive medicine.

Two activities of the State Medical Society during the past year or two have contributed to the solution of the problem of the practice of preventive medicine. The first has been the development of the system of graduate instruction under the leadership of the Committee on Public Health and Medical Education. Its lecture courses, its clinics and its demonstrations, conducted through the county societies, have stimulated the members to renewed study of all problems connected with the practice of medicine in its broadest sense. They have shown that physicians welcome instruction along the newer lines of practice when the means of study are made available to them.

The second activity that has met with cordial response from the physicians has been the frequent visits of the officers of the State Society to the county medical societies, and their attendance at the meetings of allied organizations engaged in public health.

Practically every issue of this JOURNAL during the past year has carried accounts of formal visits of the officers to important meetings of county medical societies and District Branches and health societies while unrecorded visits have been too numerous to mention. To be an officer of the Medical Society of the State of New York or a member of an important committee during the past year has meant a far greater expenditure of time and effort than most members realize. The most encouraging evidence of progress during the past year has been the ready response of the members to visits of their leaders in the State Society. Another encouraging sign is that the officers and committeemen have continued their interest after their terms of office have expired, and even taken on new responsibilities which carry much work and little honor.

The members of the Medical Society of the State of New York will profit by a careful reading of the annual reports of their officers and committees which are printed in this issue of the JOURNAL, in accordance with the resolution passed by the last House of Delegates.

# Medical Society of the State of New York

## ANNUAL REPORTS

### 1926

#### PRESIDENT'S REPORT

*To the House of Delegates*

Gentlemen

It is my great pleasure to report that during my administration the activities of the Society have continued to multiply in number and increase in complexity

The Trustees whom you elected at the last annual meeting have organized themselves and undertaken their work with great enthusiasm. If there were any doubt in the minds of any members of the Society prior to the election of the Trustees of the wisdom of such a movement, such doubt will soon be dispelled—if it has not already been—by the great service the Board will render the Society by its character of permanence. Their prime function is to appropriate, with wisdom, such funds as may be necessary for the conduct of the Society. Of course, the Executive Committee continues with the censorship it has always exercised over programs and propositions for the expenditure of monies and the Board of Trustees will not act upon any propositions except those that have received the approval of the Executive Committee. I recommend, however, that the Board of Trustees should be authorized to provide means for informing itself from time to time concerning the expenditure of funds they have appropriated. The chairman of standing committees and special committees should be asked to report at intervals of about two months, to the Board of Trustees, upon the progress made on their approved plans, with the expenditure of funds allotted to them for that purpose. Such close relationship naturally developed immediately between the Executive Committee and the Board, but such relationship has not yet been developed with the other committees.

#### DISTRICT BRANCHES

These organizations—eight in number—usually known as the District Branch Societies, in my opinion should no longer be considered Branches, but known as District Medical Societies. They should be encouraged to broaden the field of their activities and to maintain a more intimate relationship with their component County Societies.

Following the precedent set by my predecessors I attended the annual meetings of the District Branches. They were unusually well attended this year. I have been told, and I found the programs very stimulating. In ad-

dition to scientific papers, each program contained a brief review of the work done by the component County Medical Societies and a paper or two on some local public health problem. These papers, as a rule, occasioned the most general discussion, particularly the ones that described the campaign against diphtheria. It was quite evident that a certain amount of this unusual enthusiasm was due to the pains that had been taken in preparing the program.

Early in my administration the Executive Committee directed the Executive Officer to visit the Presidents of the District Branches with the idea of assisting them in developing their Societies. The President of each District Branch Society arranged a meeting of his executive officers and the presidents of the component County Societies. The conferences were all well attended and, in addition to outlining the program for the annual meeting, they discussed very freely the medical activities of their district. Guided by the reports of the value of these conferences, I recommend that they be continued and that the Presidents of the District Societies be encouraged to confer frequently with representatives of their County Societies regarding the welfare of the physician and the medical needs of the public. The organization of county health units, an activity which just now is uppermost in the minds of state officials and voluntary public health agencies, should be carefully considered and thoroughly discussed by each District president and his associates. The programs for the annual meeting of the District Societies should be made interesting and attractive. Men of outstanding ability should be invited to read papers on subjects that would have a particular interest for the physicians of that district. In the past there has been some difficulty with regard to the expense of such meeting, inasmuch as there are no dues assessed by the District Society. There was an amendment to the Constitution introduced at the last meeting of the House of Delegates, which would permit the Board of Trustees to appropriate more than \$100.00, the amount permitted at present, to the District Society to meet the expenses of the annual meeting. I recommend that this amendment be carefully considered and adopted.

I have been informed that the Medical Association of Central and Western New York, a

cians have always been willing to give their medical services freely, but they could not be expected to spend hours in persuading people to live hygienic lives, to submit to corrective operations for conditions which were not at once disabling, and in general to make use of advice for which they saw no immediate need. The unwillingness of physicians to play the part of the economist, the public official, and the social worker, led many leaders in those fields to assert that doctors were not interested in preventive medicine, and to threaten to create a new class of medical men who would engage in that line of practice exclusively. The reply of the physicians has always been that they were willing and anxious to supply the medical services and advice to all who needed it, if the other groups of the community—the financiers, the office holders and the philanthropists—would provide the extra-medical services which were also essential. The past decade or two has seen the rise of hospitals, public health nursing organizations, child welfare societies, and other health organizations, all of which depended primarily on the practice of medicine by qualified physicians. The development of practical means of coordinating all these agencies—professional, official and philanthropic—has been of slow growth. Henry James speaking of art has said that it takes a long history to make a tradition, a long tradition to create a taste, and a long taste to make art. This statement is equally true in the development of public health service and preventive medicine. Doctors on the one hand, and community workers on the other, have carried on attempts at tentative solutions of the problems with varying degrees of cooperation and success, until in the course of a decade or two their aspirations, their partial success, and their failures developed into understanding of the practical methods of work and of the recognition of the peculiar fields of activities of the various groups.

The outstanding original accomplishments of the Medical Society of the State of New York, during the past year or two has been the recognition of practical means and methods by which all health organizations can work together without intruding upon one another's peculiar fields. Those who attended the District Branch meetings last fall were impressed by the reports of the practice of public health and civic medicine by a sufficient number of county medical societies to assure the success of the newer methods of the practice of preventive medicine. The final step in the promotion of this practice has been the formation of the committee on Public Relations which is coordinating the activities of all the various agencies to the satisfaction of all the groups—the public, the physicians and the non-medical organizations—with physicians as the leaders

and authoritative advisors. This committee is beginning a work whose result in preventive medicine will be similar to that in the field of hospital establishment and administration, in which a happy coordination between all groups has been recognized for a decade. The happy birth of the new methods in preventive medicine has been accomplished only after a long period of pain and travail, which now seems to be at an end. The ripening of fruits of the oft-repeated efforts of leaders in the medical societies in the State has been possible only within the last year or two. But at the present time the medical profession of New York State may properly claim the honor of being the first to present a practical solution of the problem of the practice of preventive medicine.

Two activities of the State Medical Society during the past year or two have contributed to the solution of the problem of the practice of preventive medicine. The first has been the development of the system of graduate instruction under the leadership of the Committee on Public Health and Medical Education. Its lecture courses, its clinics and its demonstrations, conducted through the county societies, have stimulated the members to renewed study of all problems connected with the practice of medicine in its broadest sense. They have shown that physicians welcome instruction along the newer lines of practice when the means of study are made available to them.

The second activity that has met with cordial response from the physicians has been the frequent visits of the officers of the State Society to the county medical societies, and their attendance at the meetings of allied organizations engaged in public health.

Practically every issue of this JOURNAL during the past year has carried accounts of formal visits of the officers to important meetings of county medical societies and District Branches and health societies while unrecorded visits have been too numerous to mention. To be an officer of the Medical Society of the State of New York or a member of an important committee during the past year has meant a far greater expenditure of time and effort than most members realize. The most encouraging evidence of progress during the past year has been the ready response of the members to visits of their leaders in the State Society. Another encouraging sign is that the officers and committeemen have continued their interest after their terms of office have expired, and even taken on new responsibilities which carry much work and little honor.

The members of the Medical Society of the State of New York will profit by a careful reading of the annual reports of their officers and committees which are printed in this issue of the JOURNAL, in accordance with the resolution passed by the last House of Delegates.

and rather than make some statements which they probably would find difficult to defend, they chose to make no recommendations whatsoever

Our experience with the legislature this year was very satisfying. No obnoxious legislation was enacted and we were successful in having favorable consideration given the public health and workmen's compensation bills in which we were interested and the one measure which we introduced, namely, the nurse registry bill.

#### PUBLIC RELATIONS COMMITTEE

One of the greatest handicaps that medical men have had in recent years in the promotion of their work in preventive medicine has been a lack of understanding between the medical organizations and the voluntary and state public health organizations. There has always been a feeling—in some sections of the state very strong and well placed—that voluntary agencies and the State Department of Health were combined to promote conditions favorable to the adoption, eventually, of some form of state medicine. This feeling has recently been markedly accentuated by an increasing desire in voluntary agencies and departments of health for the creation of county health units.

It seemed wise to me that some effort should be made to bring order out of the chaos which appeared to exist and, accordingly, I appointed a committee of representative physicians whom I knew to be interested and to have had more or less experience with the experiments in county health unit organization, to compose a Committee on Public Relations, whose function I stated should be to confer with voluntary agencies and representatives of the State Department of Health on the methods now in use or to be employed in the promotion of public health and welfare activities where the practice of medicine was involved, and particularly the newer phase known as preventive medicine. This committee has had five conferences with representatives of one voluntary agency and, as its report will show, it has already accomplished a great deal. The members were surprised to discover that the antagonism which seemed to exist was largely mythical. There was a real desire on the part of the representatives of the other agency to cooperate with physicians and they were quite ready to accept almost every proposition made by our committee with regard to the conduct of public clinics, the care of indigents, and promotion of educational and informational campaigns.

I am so thoroughly convinced of the value of the work that this committee has begun, that I recommend that every County Society appoint a committee to cooperate with a simi-

lar committee in the State Society, to be known as the Committee on Public Relations, and that such county committee has, as its function, the development of a close relationship with every agency or organization that is doing work in the field of public health within its jurisdiction, for the purpose of developing harmony in programs of activity. I also recommend that another standing committee, to be known as the Committee on Public Relations, be created, because the work cannot be accomplished, even its first steps, in one year—and problems will continue to arise from time to time as the development of the practice of preventive medicine increases, which will demand consideration and thought for their proper and satisfactory solution.

#### ANTI-DIPHTHERIA WORK

My predecessor, Dr. Van Etten, appreciated the strategic position the State Medical Society might achieve by taking the leadership in one of the most important preventive medicine programs ever inaugurated, namely, the prevention of diphtheria by immunization of children. He organized a committee of leading physicians and public health workers, including representatives of the State Department of Health, for the purpose of coordinating and harmonizing the efforts of all organizations with the physicians' experience as to how immunization can best be accomplished. He included in this committee the chairman of several of our standing committees. The powerful influence a committee of this kind was bound to have in directing a piece of work so extensive as a state-wide campaign on diphtheria, was equally appreciated by leaders in welfare and public health activities. The State Charities Aid Association, probably the most powerful welfare association in the state, immediately asked Dr. Van Etten, as president of the State Medical Society, to become a member of its executive committee. Upon my entering into office, I, too, was invited to become a member of this executive committee, which invitation I accepted. As a member of this committee, I have found many opportunities to explain the position of the physician with regard to public health activities, not only those connected with the anti-diphtheria campaign, but with other public health activities. The discussions at meetings of this committee inspired me with the idea of organizing a Committee on Public Relations.

To return to a discussion of the work accomplished by the Anti-Diphtheria Committee, Dr. Van Etten's large committee suggested the creation of a smaller working committee, to be composed of one or two representatives of each organization. I have had the opportunity of sitting in with this committee several times during the last year, at its monthly meetings. They have kept in intimate touch with anti-diphtheria

scientific organization that for the last fifty-one years had been very active, decided this last year to discontinue its activities because of the high quality of meeting that the district Societies have been conducting. This is both a compliment and a challenge to the District Societies of that section of the state.

#### COUNTY SOCIETIES

I have been greatly gratified in my visits to the County Societies to realize how thoroughly they appreciate the strategic position which they occupy in the medical organization of this state. It has been my pleasure to visit with fourteen County Societies at a regular meeting during this last year. In every instance I found a lively interest expressed by all in the welfare and function of the Society. We have often heard it said that the excellence of a County Society depends upon the efficiency of its secretary. The truth of this has been demonstrated so often that I have no inclination whatever to dispute it, but I should like to add that, from my own observation, there are other factors in the County Society that may contribute greatly to its success. Some presidents, although their terms of office have been but one year, have been able to stimulate their Societies greatly in that time. In other instances, it has been the chairman of certain committees who have taken a leading role in the activities of the Society for a period of time. I have in mind particularly the chairman of certain committees on post-graduate instruction and public health.

A County Medical Society, like any other organization, thrives in proportion as it realizes that it has a definite purpose and responsibility which it may achieve and assume. No other local organization of medical men should be permitted to displace the County Society. It has a function because of its integrated relation to the State Society, which it cannot delegate to any other body. Other organizations may promote equally as effectively scientific study and sociability, but only the County Society can officially represent the physicians in their dealings with public health organizations or the boards of supervisors or the House of Delegates of the State Society. Therefore, I feel very strongly that the officers of the County Societies should make every effort to have meetings well attended and opportunity afforded for the discussion of all activities that arise in the county which would have an effect upon the practice of resident physicians.

#### POST-GRADUATE INSTRUCTION

We have not completed two years of special activity in programs of post-graduate instruction, and we have every reason to feel encouraged with the results that have been obtained.

A large number of the Societies have availed themselves of the offer of the Committee on Public Health and Medical Education to assist them in conducting courses of lectures on such subjects as they may select, the committee providing the lecturers without expense to the local Society.

My own County Society conducted a course of lectures on heart disease, and I believe that the Society engaged in no more profitable undertaking in the last decade. I hope that this may become a more or less permanent activity of the State Society. Physicians now, above all other professional men, feel the necessity of keeping themselves abreast of the times, because of the rapidity with which scientific discoveries are being made, some of which have had almost revolutionary effect upon the practice of medicine. There may not be the same demand for facilities for post-graduate instruction from all sections of the state. Those men who live in the vicinity of medical schools or large hospitals have facilities for keeping themselves abreast of the time, but a large number of members of our Society find it difficult, or almost impossible, to leave their practices to take courses in medical schools or clinics. Therefore, the opportunity afforded by the State Society for them to have discussed in their own County Societies the latest advancement in the practice of medicine should be considered a function of the State Society. Efforts should be made to interest medical schools and the larger hospitals in developing themselves as centers for post-graduate instruction of this character.

#### MEDICAL PRACTICE ACT

The amendment to the Medical Practice Act, which was enacted last year, is working out very satisfactorily. The Department of Education has employed five inspectors and the attorney general has appointed one of his deputies to take charge of the enforcement of the law. Together these agents have already brought to prosecution a number of cases. This vigorous enforcement of the law is having a noticeable effect upon the practice of chiropractic. Many have forsaken their practices in New York State and gone to other business or to other states.

The legislative committee appointed to investigate chiropractic held several hearings, where chiropractors and physicians were invited to give such information as they chose concerning chiropractic and the desirability of licensing those who would practice it in this state. Their report at the end of the legislative season was very brief and unsatisfactory. They confessed that the time they had taken to investigate the matter was entirely too short for them to bring out any worth-while report,

### TRI-STATE CONFERENCE

About two years ago, representatives of the Medical Societies of New Jersey and Pennsylvania approached us with the suggestion of holding a conference between the officers of the three Societies, for the purpose of discussing certain medical questions that involved the three states, with the idea, of probably suggesting uniform legislation

The first meeting was held in Atlantic City a year ago last November. Since then there have been four conferences, one in Philadelphia, one in Atlantic City and two in New York, at which such subjects as, "The Nurse Question," "Workmen's Compensation," "Anti-Quack Legislation" and "Relations of the Medical Organization to voluntary Public Health Agencies"—have been discussed with great profit to all. We are learning that some of the problems that give us the greatest concern in this state, are common to the three states, and, in some instances, they have given us suggestions with regard to their solution, while to the solution of others we have been able to contribute from our experience.

These conferences should be continued, in my opinion, not only because of the advantages which arise from a discussion of common problems, but for the sake of developing a closer fraternal spirit with these two powerful neighboring Societies.

### SECRETARIES' CONFERENCE

The Executive Committee authorized the Secretary and the Executive Officer to call a conference of the secretaries of the County Societies. Such conference was held in Albany and it was my privilege to be present. Almost every county was represented. In a few instances, the secretaries were on vacation.

The conference considered the present conditions of the County Societies and suggestions for improving them. From conversations I have had with secretaries at County Society meetings since that conference, I am convinced that the State Society should provide that such a conference may become an annual affair.

### JOURNAL

Too much credit cannot be given to the Editor-in-Chief of our JOURNAL for the splendid type of publication he has given us. The section on Medical Progress, which was begun last year, has increased the value of the JOURNAL materially. There was, also, this year considerably more space devoted to the reports of County Medical Society meetings and to local county news. This portion of the JOURNAL is growing very valuable and will continue to do so, depending upon the cooperation the editors receive from County So-

cieties. In certain states each County Society has one of its members appointed annually as reporter, whose function is to keep the State Journal informed of the activities of that County Society. There is probably no need for such appointment, but there is great value in reporting the activities of a County Society in the JOURNAL, where other County Societies can read and inform themselves of activities outside their own county. A number of the larger County Societies issue bulletins of their own. They do so because much of the material that the bulletin contains would not have the same interest to physicians residing in other counties, but the columns of our JOURNAL should be used by every county for all that would be of interest to any other county in the state. There are problems that are common to many counties, the solution of which no one county can satisfactorily accomplish, but if each were, from time to time, to give its experiences in the columns of the JOURNAL, where others could read them, satisfactory solutions might be expected.

The JOURNAL should not be simply a means of distributing scientific papers, it should also be the means of disseminating experiences—whether of successes or failures—of the County Societies' activities. Some physicians have told me that they begin to read the JOURNAL at the editorial page.

### DR OWEN E. JONES AND DR. WILLIAM FRANCIS CAMPBELL

It is with a sense of deep sorrow that I announce to you the death of two former presidents, during the past year. Dr. Owen E. Jones, a victim of his own zeal, suffered a breakdown while serving as president of this Society, from which he never recovered. To the last he retained a great interest in the growth of the Society and cherished the greatest devotion for its future achievements. Dr. William Francis Campbell will long be remembered for the unvarying devotion with which he served the Society. He probably was a close warm friend to more members than any of his associates. The Society is suffering a great loss in the death of these two men and I recommend that when this House of Delegates adjourns, it does so in honor of Dr. Owen E. Jones and Dr. William Francis Campbell.

Having come to the end of my term of office, I want to express my sincere appreciation of the honor you bestowed upon me a year ago. I trust that I have merited the confidence you then placed in me. I assure you that I have never undertaken any piece of work to which I have devoted more of my time or from which I have gotten greater stimulation and satisfaction, than I have from serving as your president. It is not with a feeling of having completed a task that I address you, I am sorry to say, because I thoroughly appreci-

work everywhere throughout the state, and, by reviewing the activity in each community, they were able many times to make suggestions to the local leaders as to how their campaign might be improved.

Through this cooperative committee, the activity of the practicing physician has been more fully appreciated and special efforts were made to assist him, for instance, placards were prepared for physicians' offices. These were distributed in most instances through the County Medical Society. Enormous posters were displayed on bill-boards which, in not a few instances, was definitely stimulated by the County Medical Society. Probably no other public health movement was attended by such a degree of success. There have been fewer cases of diphtheria and fewer deaths from that disease in the State of New York during the last year than in any year since records have been kept. Immunization of children between the ages of birth and ten years is being done in every section of the state by private physicians, school physicians and the health officers. In some instances the work has taken the nature of a campaign in which the lay organizations have taken the lead in stimulating a desire on the part of parents to have their children immunized, and the physicians have cooperated by assisting with certain public clinics. In other places, the physicians have taken the lead and invited the voluntary agencies to assist. In some cases the Medical Societies have taken the initiative and, without much publicity, have urged their members to immunize the children of their families. All of these methods have been more or less effective and which scheme is best, is difficult to determine.

In my opinion, the position of the physician in the practice of preventive medicine is but slightly different from that which he occupies in the practice of curative medicine. A sick individual knows he needs the attention of a physician, and his associates are equally eager that he should be attended by a physician if his affliction is contagious. And when the object is to prevent the appearance of a contagious disease or the development of degenerative diseases, the initiative should again arise with the patient or the public, who should have as lively an interest in maintaining—as they now have in recovering—their health. However, for this condition to prevail, it is necessary that the individual and the public should be thoroughly informed concerning the dangers with which communicable and degenerative diseases threaten them. The physician can take a part in the dissemination of this information, but he should not be asked to undertake such task alone.

The progress the anti-diphtheria campaign is making seems to justify a deduction of this kind. Where the public has taken a lively interest in

protecting its children against the inroads of diphtheria, approaching 100 per cent of the children have been immunized, on the contrary, where the public has not been interested, there has been much less demand for immunization, in spite of the activity of the physicians. The ideal condition is that the parents of children should realize the value of immunization and have the same accomplished by their family physician soon after a child reaches the age of six months. The slogan of the Anti-Diphtheria Committee is, "No Diphtheria after 1930." While this will not actually be accomplished, there is no doubt in the minds of all those who have been watching the progress made in the immunization of children but that diphtheria will soon become as rare as typhoid and smallpox are today.

#### HEART COMMITTEE

Public attention has for the last several years been directed to the increasing number of prominent men and women who, in the prime of life, are stricken down by some form of heart disease. Several organizations have made the study of heart disease a part of their function, but it seemed to me that there was an opportunity here for our Medical Society to do a large piece of research. I requested and secured authority from the Council to appoint a committee of eminent heart specialists, for the purpose of making an investigation into the problem of heart disease. That committee, although appointed but a few months ago, has already collected some very valuable material and data. The task is so extensive that it was understood when the committee began, that it could not be expected to complete its work this year. I recommend, therefore, that the committee be authorized to continue the work another year.

#### AMERICAN PUBLIC HEALTH ASSOCIATION

I was invited to attend the annual meeting of the American Public Health Association in Buffalo last October. This is a powerful organization, with members from every state in the Union and the Dominion of Canada. It is one of the oldest organizations of its kind and one of the most active. It is particularly interested in the promotion of such public health activities as are discovered of value through laboratory research or experimental demonstration. Many states have a local public health organization which affiliates with the national. In New York State the place of a local organization is taken by the Sanitary Officers' Association, whose membership is almost entirely drawn from the health officers of the state. This Sanitary Officers' Association holds an annual meeting in conjunction with a conference of health officers and public health nurses, called by the commissioner of health. This year the conference was held in conjunction with the annual meeting of the American Public Health Association.

retary respectfully requests that all such be sent to the Society's office

For the purpose of clarity and expediency, all resolutions and motions offered in the House of Delegates should be in writing and in duplicate, one copy for the Reference Committee and one for the Secretary's file

The Secretary suggests that the habit contracted of late years of deferring action on resolutions and referring them to the Council should be done away with as far as possible, the House being more representative of the Society and its floor being open for debate

#### DISTRICT BRANCHES

In accordance with a time honored custom, the Secretary visited the Annual Meetings of the eight District Branches. The meetings were found to be well attended, sincerely enthusiastic and interested in the work, with programs of real worth

It is being realized more and more that these District Branches fill an important place and have a distinct value in the economy of the State Society. They afford the membership an opportunity to get away from the narrower confines of the County Society, form new contacts and broaden their interests

The Presidents of the Branches are Councilors of the State Society and should keep by a system of County Society visitations, the counties informed of what is going on in the State Society, and themselves in close touch with the work and needs of the County. It is the opinion of the Secretary that these District Branches can do much toward the future progress of the State Society

#### CONFERENCE OF SECRETARIES

During the year there have been held two conferences of County Secretaries, one in New York City during the Annual Meeting and one in Albany on September 2. These conferences have been of great benefit to the Society and to its component county units

The Secretary recommends that they be continued and that they take the same form of instructive discussion instituted at the Albany meeting

The Secretary had the pleasure of attending the American Medical Conference of State Secretaries and Editors and to the New York Secretary fell the honor of being selected to present the opening paper in the discussion

#### EXECUTIVE OFFICER

The Secretary feels that he would be derelict in his duty of making a correct report without especially mentioning the work of the Executive Officer, work that has been of great benefit to the Society

His legislative duties have increased in extent and importance as the years have gone by and he has become more intimately known to and influential among the legislators

Of equal value has been his work as a liason officer between the different county societies and between the societies and various welfare and health organizations. Commendable also has been his work in the District Branches where he has taken over the work assigned by the By-laws to the Secretary with far more benefit to the Branches and the Society than could be done by that officer

His work in the Secretaries' Conferences and the Tri-State Conference in New York City, together with his work in connection with the Committee on Nursing and the Public Relation Committee, are all well worthy of mention

#### MEMBERSHIP STATISTICS

		<hr/>
Membership, January 1, 1927		10,700

The list of honor counties whose membership shows all dues paid for the year is as follows: Cayuga, Chemung, Delaware, Essex, Fulton, Greene, Lewis, Nassau, Orleans, Rockland, Schoharie, Schuyler, Seneca and Tompkins

The Secretary takes pleasure in extending his thanks to the Business Manager for her valuable assistance and effective work, to the Executive Officer for his support and willing cooperation and to the Councilors for the cordial greeting and hospitality extended to him at the District Meetings. He thanks the members of the Executive Committee and the Board of Trustees for their courteous consideration of him as Secretary of those respective bodies and extends his sincere thanks to the President for his many acts of friendly kindness and his never failing courtesy

The Secretary records with sorrow the deaths of two former Presidents of the Society, Dr. William Francis Campbell and Dr. Owen E. Jones. Appropriate action in their memory has been taken by the Council

Respectfully submitted,

March 15, 1927

D S DOUGHERTY,  
Secretary

ate that the work of this Society—now more than one hundred and twenty years old—is still in its youth. Annually we are contributing, through our activities, to the great record of accomplishment in medical progress. The public is looking to us more confidently than it ever has done, for assistance in the solution of the great problem of public health. I wish that I might have had an opportunity to visit each County Society as I did each District Branch Society, but that was impossible for several well-known reasons.

Before closing, I wish to make one more recommendation, and that is that the expense allowance to the president be increased. Each man occupying this position henceforth, is going to

find it necessary that he devote almost his entire time to the demands of the Society, and much of that time will be spent in travel. This fact should be realized by you and the proper provision made.

I would be very ungrateful if I did not express a word of appreciation for the staunch support afforded me by all of the officers and committees. There has never been a year of greater activity. Your president-elect has been my closest associate throughout the year and it is with the greatest confidence in the future progress of the Society, that I retire before him.

GEORGE M. FISHER,  
President

March 15, 1927

## REPORT OF THE SECRETARY

*To the House of Delegates—  
Gentlemen*

The Secretary again has the honor of submitting a report to the House of Delegates.

In his report of last year, he endeavored to lay stress upon the great need of business efficiency and organization and took occasion to point out some of the faults and fallacies that, in his opinion, had tended to develop a system, or rather lack of system, in the conduct of affairs, not consistent with modern ideas and methods. He outlined also, certain changes that he deemed necessary to produce results that might benefit the Society. He has worked hard and faithfully during the year to accomplish this end but feels that although considerable progress has been made, much still remains to be done.

He wishes to emphasize two statements made in his last report. First, the Secretary, *per se*, concerns himself only with the business side of the Society's affairs, with the conduct of his office and the relation it bears to the component County Societies to the officers and to the committees, legislation and policies, he is not concerned in except as an individual member. Secondly, the Secretary of the Society, being also Secretary of the House of Delegates, of the Council, of the Executive Committee, of the Censors and of the Board of Trustees and a member of all standing committees is essentially the business officer of the Society and should be recognized as the head of the Society's office *de facto* as well as *de jure*.

To the uninitiated, the office may seem easy and pleasant, to one who has intimate knowledge of it, the burden is heavy and without the friendly consideration and cooperation of the members and officers the Secretary would not be able to carry it.

### THE SOCIETY'S OFFICE

Here the greatest improvement is shown. The antiquated headquarters with their obsolete equip-

ment are things of the past and the Society now occupies a pleasant and commodious suite of offices on the fourth floor of the new Academy of Medicine building. The office furniture and other appliances have been brought up to date, the filing system is excellent and a more thorough system of bookkeeping has been adopted.

With the advent of the Board of Trustees, the financial affairs of the Society have taken a more business like aspect and a proper correlation of the Secretary and Treasurer's offices with the Board has been established by a system of monthly audits. There is, however, still room for improvement.

The Editorial Department has been separated from the Secretary's office and now occupies suitable quarters on the fifth floor of the building with a clerical staff of its own.

The Secretary feels that no more can be done at present but believes that in the time to come the *Directory* should be placed with the *JOURNAL* under a Publication Department and that a proper Financial Department should be formed separate from the Secretarial Department. With such a division of activities, each functioning individually, but correlating through the business manager and under the general supervision of the Secretary, a nearer approach to a perfect business organization would be made. It should be remembered that although primarily a medical society, the Medical Society of the State of New York is a chartered membership corporation working under and subject to all the legal rules and regulations governing such corporations.

### REPORTS AND COMMUNICATIONS

All reports and official communications should go through regular organized channels, only in that way can correct records be kept and overlapping and confusion be avoided. Many documents of value which should be properly filed for future reference are still in the hands of ex-presidents and former committee-men. The Sec-

ADVANCE DUES, 1927

## REPORT OF TRUSTEES

*To the House of Delegates*

Gentlemen

The Board of Trustees of the Medical Society of the State of New York met on May 14, 1926 at which time they organized Dr George M Fisher, President of the State Society, presided as temporary chairman

The motion was adopted, until otherwise decided, that the member serving the last year of the term for which he was elected be Chairman of the Board and the member immediately succeeding him in term of service be Vice-Chairman

In accordance with this decision Dr Frederick H Flaherty became Chairman and Dr Arthur W Booth, Vice-Chairman In accordance with the By-Laws, Dr D S Dougherty became Secretary

The Board has held nine regular meetings in New York City It is very gratifying that there has been a very full attendance of the Board at each meeting Only on one occasion has there been more than one member of the Board absent at a meeting

One of the first acts of the new Board was to adopt the budget as presented by the Executive Committee for the year ending May 15, 1927

Monthly audits of the Society's accounts were ordered to be rendered to the Board at each monthly meeting, the Board employing an expert accountant for this purpose

\$25,000 00 of the Society's funds were invested in bonds, acceptable to savings banks, in lots of \$5,000 00 each and deposited in a safety box in the vault of the Chase National Bank and \$15,000 00 more will be placed in savings banks in units of deposits of such size as to obtain the maximum rate of interest

It was decided that the power of drawing checks on the investment funds be vested solely in the Board of Trustees and that all five of the elective members' signatures be necessary for the withdrawal of such funds

The Board also made a rule that no expenditures, except those incurred for routine business, should be paid until examined and endorsed by the Board of Trustees

Mr Lloyd Stryker, our Counsel, and Dr C Gordon Heyd, our Treasurer, were in attendance at several of our meetings where their advice and counsel were needed

Upon recommendation of the Executive Committee it was ordered that the sum of \$1 00 from the dues of each member be applied as a subscription to the directory and also \$1 00 from the dues of each member be applied as a subscription to the JOURNAL

Respectfully submitted,

FREDERICK H FLAHERTY,

*Chairman*

March 15, 1927

---

## REPORT OF THE BOARD OF CENSORS

*To the House of Delegates*

Gentlemen

The Board of Censors presents the following report

By reason of appeals from decision of two County Societies, three meetings have been held

On May 13, 1926, the Board convened to hear the appeal of Dr Harry Benjamin from the decision of the Medical Society of the County of New York, the County Society having denied his application for membership After due trial, both sides being represented and heard, the Censors rendered their decision in favor of the Society Notice of appeal to the House of Delegates was served on the Secretary but has been withdrawn

On December 10, 1926, the Board was called together to hear an appeal of Dr C Everett Field from the action of the Medical Society of the County of Queens expelling him from membership Three sessions were held, two on that date and an adjourned session on January 27, 1927 The appellant was represented both in person and by counsel, the Society resting its case upon the stenographic report of the testimony taken at the trial The Board unanimously affirmed the decision of the County Society

Respectfully submitted,

D S DOUGHERTY,

*Secretary*

March 15, 1927

## REPORT OF THE COUNCIL

To the House of Delegates—  
Gentlemen

The Council has the honor of presenting the following report which includes those of the Executive Committee and Committee on Publication

Three meetings have been held, May 13, April 1, and December 9

In accordance with the provision of the By-laws governing the constitution of an Executive Committee, the following members of the Council were elected to serve with the President and the Secretary John E Jennings of Kings, E Elliot Harris of New York, Harry R Trick of Erie, John A Card of Dutchess and Nathan B Van Etten of Bronx

Other appointments made were Chairman of Committee on Arrangements, F J Schnell of Niagara, Editor-in-Chief, O S Wightman of New York, Executive Editor, F Overton of Suffolk, Executive Officer, J S Lawrence of Albany and as Committee on Publication, the Speaker, the Secretary and N B Van Etten

The Council sanctioned the appointment of three important special committees to study the Nursing Problem, N B Van Etten, Bronx, Chairman, on Public Relations, George W Cottis, Chautauqua, Chairman, and a committee for the study of Cardiac Disease, R H Halsey of New York, Chairman

The conferences with the officers of the Medical Society of the State of Pennsylvania and that of New Jersey have been continued and reports of their proceedings published in the JOURNAL

Two sections, one on Dermatology and Syphilis and one on Industrial Medicine were added to the Sections of the Scientific Session

On June 15, the members of the Council gave a dinner in honor of the Chairman of the Committee on Legislation, Harry L K Shaw; and on January 27, the Society through the Council tendered a testimonial dinner to Wendell C Phillips, President of the American Medical Association

## EXECUTIVE COMMITTEE

The Executive Committee has held meetings on the second Thursday of each month

The business transacted at these meetings has consisted mainly of the routine work necessary to the proper functioning of the Society, in the carrying out of the instructions of the Council, in the preparation of the budget, in the examination of the various bills and expense accounts and in the endorsement of them for reference to the board of Trustees. It will be seen from this that the Executive Committee is the business committee of the Society

## COMMITTEE ON PUBLICATION

This Committee has, in accordance with the By-laws, supervision over all publications of the Society and in the performance of this duty has held conferences with the Editor as the occasion demanded. The Committee feels that the thanks of the Society are due the Editor and his staff for the wonderful work they have done in raising the standard of the JOURNAL and in placing it upon a more substantial financial basis

The following shows the 1926 Receipts and Expenses, exclusive of stenographers' salaries and incidentals

<i>Receipts</i>	
Advertisements and Sales	\$29,005 17

<i>Expenses</i>	
Salary of Editors	\$ 6,700 00
Printing, postage, mailing	28,936 35
Commissions	7,611 54

The cost of the JOURNAL to the Society shows a decrease in 1926 over 1925 of \$5,722 40. This decrease is due to an increase in the receipts from advertisements and sales of \$10,203 00, and has been accomplished in spite of an increase in expenditures due to the JOURNAL now having its own editorial offices, equipment and clerical force, as well as a general expansion in all directions

*Directory*

1926 Receipts and Expenses, exclusive of stenographers' salaries and incidentals

<i>Receipts</i>	
Advertisements and Sales	\$ 9,080 50

<i>Expenses</i>	
Printing, postage and delivery	13,509 96
Commissions	1,161 75

The *Directory* shows an increase in the cost to the Society of \$921 00. This is due to an increase in the size of the edition as well as in the size of the book and to the using of a better quality of paper for the cover. It is not due to a decrease in advertisements and sales which show an increase over 1925 of \$443 00

The Council and its Executive Committee have endeavored to carefully consider and act upon the many resolutions and recommendations referred to them by the House of Delegates but the absence of proper data has frequently made such study a matter of great difficulty, in fact, in some instances, impossible

Respectfully submitted for the Council,

D S DOUGHERTY,

March 15, 1927

Secretary

as the physician is concerned, it simply recognizes that if he carries out the regulations of the Harrison Law, he will be complying with the State Law. The bill provides for the commitment of addicts and probably this will be difficult of enforcement, because in most sections of the state there are no available hospitals suitable for the treatment of addicts. The introducers of this bill had a companion bill which would have licensed private hospitals for the care and treatment of drug addicts, to which those apprehended by the law might be admitted, but this bill failed of passage.

The most important legislation in recent years was that enacted last year when the amendment to the Medical Practice Act became a law. It takes many months to build up the machinery for its enforcement and to get it in smooth running order, but in a short space of time it has worked out most successfully. A Committee on Grievance was appointed by the Board of Regents, composed of prominent physicians from various sections of the state, and at their first meeting Dr Orrin Sage Wightman, past-president of this Society, was elected chairman, and Dr Frederick H. Flaherty, of Syracuse, secretary. The attorney general designated two deputy attorneys general for full time work in connection with the prosecution of violators of this act. Five inspectors have been appointed by the Department of Education, who are spending their entire time investigating cases referred to them by the Grievance Committee and in seeing that the features of the bill are being carried out. One very marked effect in the enactment of the provision prohibiting chiropractors to use the word "Doctor," has been that nearly five hundred chiropractors have left the state. Their work is being watched very carefully and it is reported that a large number of chiropractors are requiring patients to sign affidavits before treatment will be administered, stating that they will not appear in court against the chiropractors. This will very likely limit the number of their patients.

The Department of Education has received many complaints which it has been able to remedy and rectify by correspondence and through the efforts of the attorney general, without resource to the courts. The registration of physicians has been remarkably successful and over 16,000 have complied with the law. A list of these physicians will be mailed to each member of the medical profession at the end of April or early in May. The list is now in the hands of the printer, but there has been some delay owing to the severe illness of the assistant in charge of this work.

The provision relating to physiotherapists has resulted in the licensing of comparatively few such practitioners. Upwards of three hundred applications were received by the Department of Education and of that number, thus far, less than seventy-five have been licensed and it is not probable that the number ultimately licensed will exceed seventy-five. There is already a movement on foot to establish a thorough, honest school of physiotherapy within the state, so after a few years everyone licensed to practice physiotherapy will have graduated from a school recognized by the Board of Regents. At present there is no such school.

We wish to extend to the officers of the State Society and to the chairmen and officers of the County Societies, our thanks and appreciation for the splendid support they gave us during the year, and we hope they will support the Committee as staunchly in another year. Since there were so few controversial bills introduced in the early part of the session, we did not think it necessary to hold a conference of the County Society chairmen in Albany this year.

The chairmen of the Public Health Committees of the Legislature—Senator Webb in the Senate and Dr. Lattin in the Assembly—have done very valuable work in the interests of the medical profession, and they should not go unrecognized. There has been a very marked desire on the part of the legislators, as a whole, to refer to the Committee on Legislation for advice regarding medical legislation.

We wish to call attention to the very cordial and friendly relations which existed between our Committee and the State Charities Aid Association, the American Association for Medical Progress, the Department of Education, the State Department of Health and the Department of Health of New York City. Their cooperation has aided very materially in preventing the passage of undesirable bills.

The Executive Officer, Dr. Lawrence, has been on the job in season and out of season, and he has been on the firing line throughout the entire legislative session. His acquaintance with the legislators has been most valuable and the successful year of medical legislation is very largely due to his efforts.

The offices of the Legislative Bureau are to be moved from their location at Pine and Chapel Streets to a more satisfactory location in the City Savings Bank Building, 100 State Street.

Respectfully submitted,

HENRY L. K. SHAW, *Chairman*  
April 1, 1927

## REPORT OF THE COMMITTEE ON LEGISLATION

*To the House of Delegates—*

Gentlemen

Your Committee on Legislation takes pleasure in reporting that it has just completed a year of rest and peacefulness, following the decade of strife attending our efforts to secure an amendment to the Medical Practice Act, which we were last year successful in having enacted.

The last session of the Legislature was, on the whole, entirely satisfactory with regard to legislation affecting the interests of the medical profession. The lull after the storm of last year was very noticeable and the legislators, in the main, seemed content to allow the Medical Practice Act full opportunity to show its value and not to pass any legislation that would affect its character or interfere with its effectiveness. On the closing day of the 1926 legislature a committee to investigate chiropractic was appointed at the instigation of the chiropractors themselves. The joint legislative committee held five hearings, three of them devoted to taking testimony of the chiropractors and two for the medical and educational side. Your Committee at the outset offered any help or assistance, but the committee wished to be entirely impartial and did not deem it wise to have the medical profession actively connected with their deliberations, in fact, one hearing was held without your Committee being notified. It was felt that the Counsel of the Society should represent us at the hearings and that the educational qualifications of the chiropractors should be the main consideration and that we should not enter into a discussion of the relative merits of therapeutics and chiropractic treatments. This committee submitted its report on the 15th of March and made no recommendations either for or against chiropractic. The report was remarkable for its brevity and failure to arrive at any conclusion. It did not make any request to have the committee continued. In the main the report could be considered as favorable to the medical profession.

Your Committee reintroduced the nurse registry bill, which was prepared by the Society last year and through conversation with committee chairmen and other legislators, explained its intent and the demand on the part of the public for such protection as it offered. It passed both houses with no opposition, and was in time signed by the Governor and is now Chapter No. 320 of the Laws of 1927.

There was an effort on the part of the chiropractors to pass two bills, one which would have removed them entirely from the jurisdiction of the Medical Practice Act. Another would have enabled physiotherapists to practice without medical supervision. A determined effort was made to pass these bills during the closing days of

the legislature and the chiropractors were able to marshal very strong political influence. It was for this reason that your Committee sent urgent telegrams to the chairmen of County Committees asking for their influence in reaching their local legislators. This had great effect and undoubtedly deterred the leaders from permitting these bills to pass.

The chiropractic bill was probably the most vicious that has been introduced in many years and it is a decided victory for the medical profession to have been able to kill the bill by having it retained in committee.

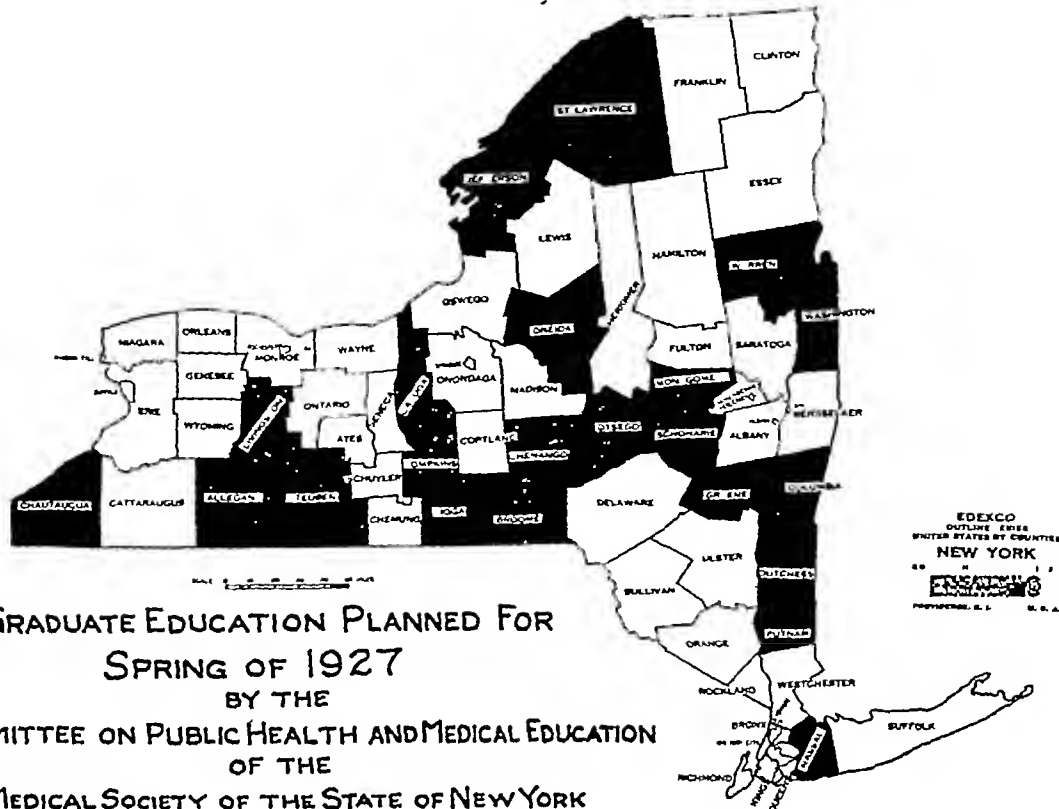

The Labor and Industry Commission made a report toward the close of the session and recommended certain legislation. They did not recommend the reorganization of the medical division as was attempted during the two preceding years, and most of the bills that they recommended which would have affected the practice of medicine, were either defeated or have since been vetoed. This Commission has been continued and we hope will give more attention to the medical phase of the Workman's Compensation Law.

The anti-vaccination and the anti-vivisection bills were introduced, as usual, but received no more consideration than in previous years.

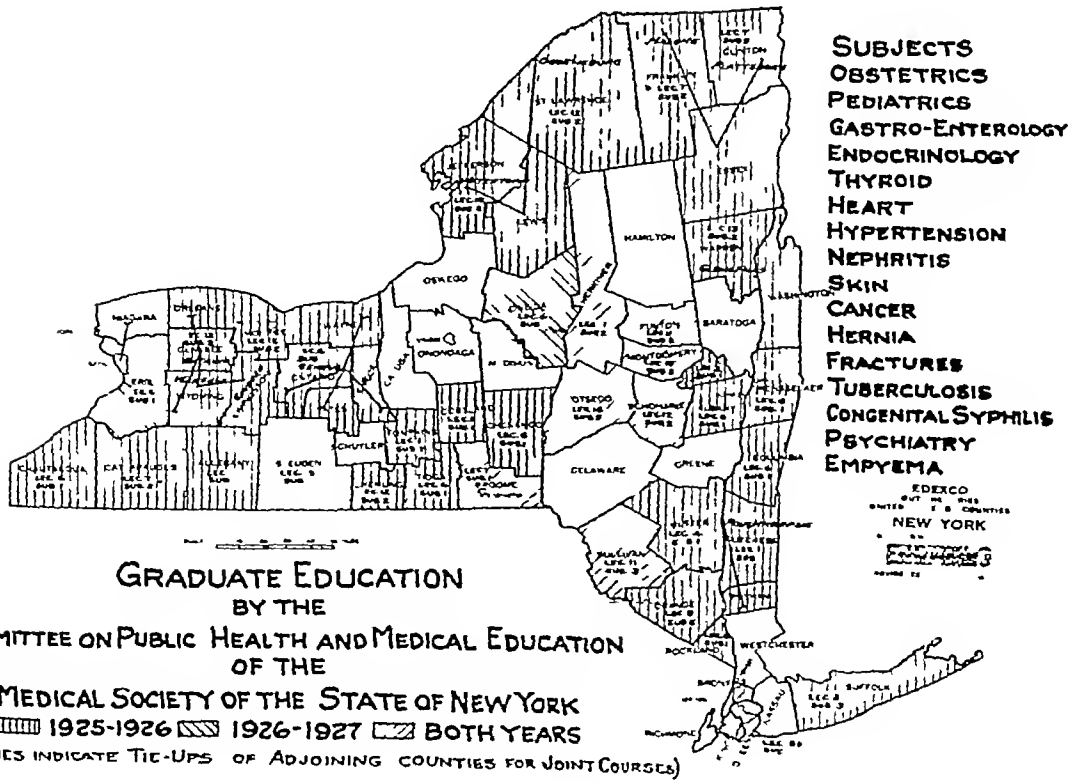

The optometrists, a portion of whom are legally using the title "Doctor," endeavored to have the law amended so that they might all use the title, providing they followed their name with the word "Optometrist." This bill passed both houses and is now in the hands of the Governor. Your Committee opposed the passage of the bill and requested the Governor to veto it, on the ground that the designation of "Doctor," in connection with the healing art, should be used only by the licensed physicians of the state.

The osteopaths renewed their efforts to secure license to do minor surgery, administer anaesthetics, narcotics and antitoxins. We recognize that inasmuch as they are permitted to do obstetrics, they should have the privilege of administering anaesthetics and narcotics, but we strenuously opposed granting them a license to do minor surgery on the ground that there is no adequate definition of major surgery. Your committee's opposition was specifically based on the fact that with the passage of the medical practice act in 1912, over 400 osteopaths were licensed to practice osteopathy who had never received instructions in surgery nor in the use of anaesthetics, etc. This bill is now in the hands of the Governor.

For a number of years the members of the Bar Association have been endeavoring to have enacted a narcotic drug law. This year they continued their efforts and finally succeeded in having their bill passed by both houses. So far

**GRADUATE EDUCATION PLANNED FOR  
SPRING OF 1927  
BY THE  
COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION  
OF THE  
MEDICAL SOCIETY OF THE STATE OF NEW YORK**

## REPORT OF THE COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

To the House of Delegates  
Gentlemen

### GRADUATE EDUCATION

During the past two years the Committee on Public Health and Medical Education has carried graduate medical education to 49 counties of the State. Lectures and demonstrations, with patients when possible, have been given in obstetrics, surgery, pediatrics, gastro-enterology, endocrinology, hypertension, nephritis, dermatology, syphilis, psychiatry, urology, and the chest, including tuberculosis, empyema and cardiac disease.

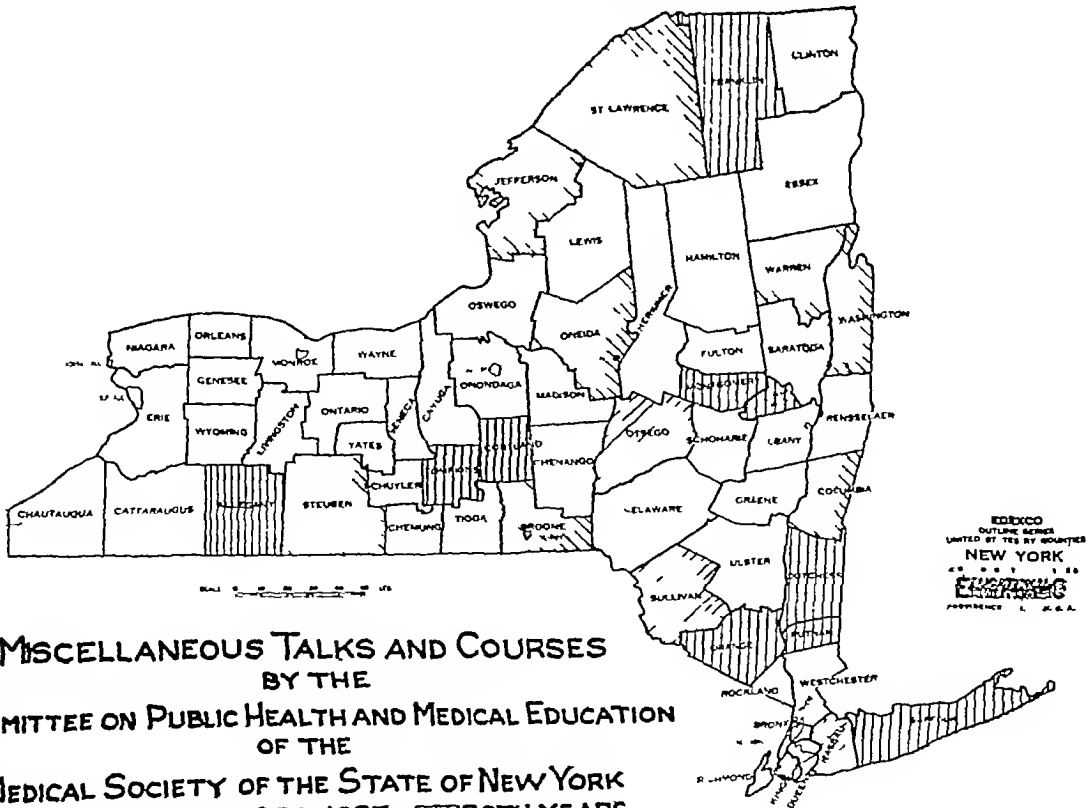

For the most part these lectures are scheduled to run from one to two hours on the same day and hour each week for six successive weeks. Each county, however, may have as many lectures as it wants. Nassau is now having its second series of 20. Montgomery covered hypertension in an intensive course of eight weeks, one day a week, long sessions, the lecturer cooperating with a dietitian, checking results from week to week on the same patients. Oneida's course in cardiac diseases, although only six periods, covered a wide range, and much time was given to the presentation of cases. In Monroe, daily lectures were given

for two weeks in obstetrics and pediatrics, and this plan secured excellent attendance.

When possible, courses have been arranged in adjoining counties, so that lecturers may cover more than one county in the same day—afternoon in one county and evening in the other, or at one central point for two or more counties. At no time, however, has any effort been made to save lectures at the expense of good attendance.

Since the publication of our last annual report, courses in obstetrics have been given in the counties of Cattaraugus, Chautauqua, Clinton, Essex, Franklin, Genesee, Monroe, Nassau, Orange, Orleans, Otsego, Rockland, Schoharie, Steuben (Corning), Tioga, Ulster, Warren, Washington and Wyoming. Courses in pediatrics have been given in the counties of Albany, Broome, Chemung, Chenango, Columbia, Erie, Fulton, Herkimer, Jefferson, Monroe, Nassau, Niagara, Ontario, Rensselaer, St Lawrence, Seneca, Steuben (Hornell), Wayne and Yates.

Courses have been given in hypertension in Montgomery, gastro-enterology in Sullivan and Nassau, cardiac disease in Oneida, and single talks in cardiac disease in Cortland, Otsego,

**MISCELLANEOUS TALKS AND COURSES  
BY THE  
COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION  
OF THE  
MEDICAL SOCIETY OF THE STATE OF NEW YORK**  
 ||||| 1925-1926    ▬▬▬ 1926-1927    ▤▤▤ BOTH YEARS

immediately interested in the individual. If a procedure of this kind is to be a permanent success, it should be very nearly salable on its merits to those most concerned.

Immunization of those unable to pay for medical service should not wait for the development of any program, but details for handling this phase of the subject should receive the approval of the county medical society. In Schenectady arrangements can be made whereby free cases can be cared for by the physician of their choice after certification by the health nurse or investigator familiar with the individual case.

The hazard of sickness and death from diphtheria is approximately equal to that of automobile accidents (153 to 141 Metropolitan 1926 experience). In Schenectady, with a pre-school death risk of less than one in 1,500 per year per individual child, we are not dealing with a risk of a magnitude such as usually excites the average parent to any great amount of fore-sighted activity. Actually there have been no deaths from diphtheria in several months, yet with almost a zero danger immunizations are proceeding at a rate nearly twice that of the birth rate of the community. A permanent rate equal to about 90 per cent of the birth rate will represent approximately 100 per cent success. Work will be carried on from year to year without an unsustainable amount of effort.

Most county societies have endorsed the general immunization idea, but so far as we know, no definite program has been developed except in Erie, Montgomery, Orange, Schenectady and the five county societies of the City of New York.

#### PRESS COOPERATION

Syndicating of medical information for popular distribution through the press is an excellent idea, but with our present limited organization it is still impracticable. Plans are now being made, however, to place the Hygeia clip sheet in the hands of editors of the larger newspapers of the State.

We welcome the assistance of all agencies organized in the interest of public health, yet we feel that the main burden of publicity must fall upon the physician, individually, or as organized in state or county groups.

#### ORGANIZATION AND EXPENSES

The office of the Committee is in the Library Building of the Medical Society of the County of Kings, which generously gives us space and provides us with secretarial help of a high

order, at the cost only of hourly stenographic service. A heavy correspondence has been handled with despatch, and an excellent file of state-wide facilities and opportunities for graduate medical education has gradually accumulated.

To date about \$2,000.00 has been expended, approximately \$1,200.00 for small honoraria and traveling expenses of teachers, and the balance for secretarial service, office supplies, telephone calls and telegrams. We have requested an official audit of our accounts.

The State Department of Health has borne the cost of most of the lectures in obstetrics and pediatrics, and is continuing to respond to our request for such courses where they have not already been given.

Our most urgent need is for competent full-time secretarial help to relieve the Chairman of the vast amount of detail work which has demanded an unusual amount of time and effort. The burden has been heavy, not only upon the Chairman but upon the 65 men who have co-operated in our teaching plans.

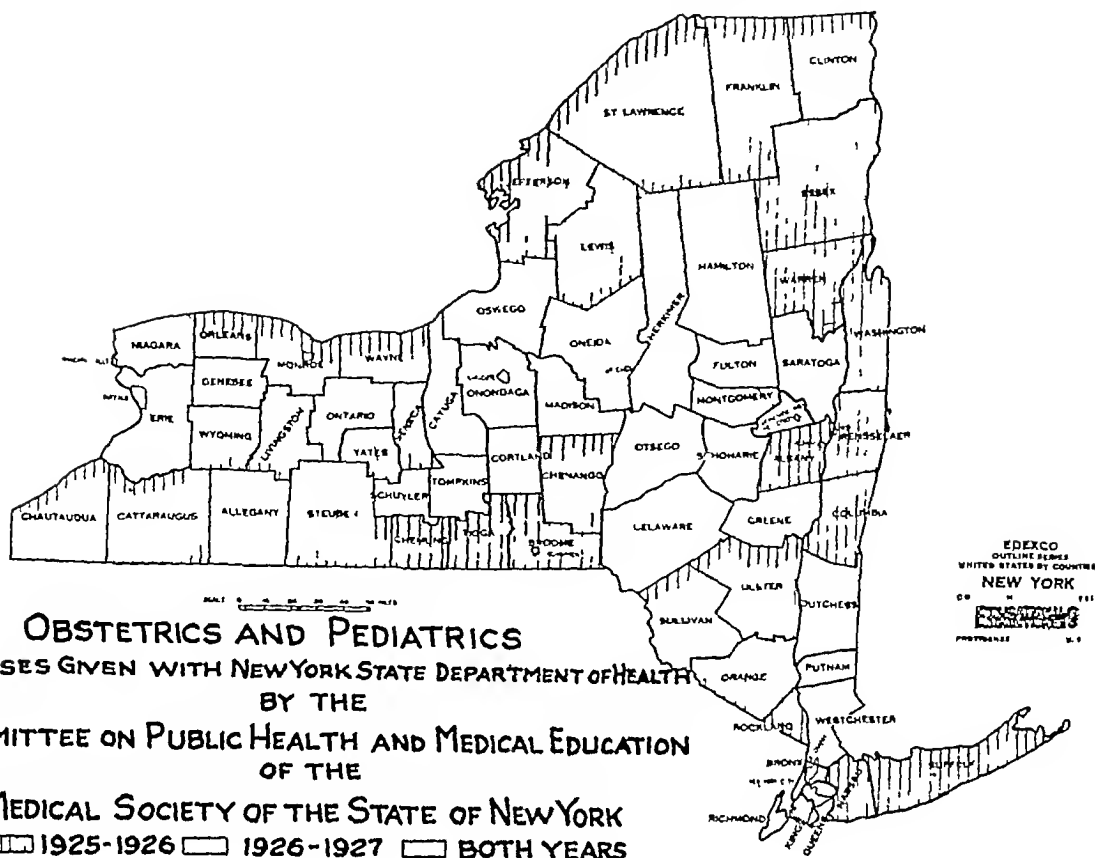

Planning courses by correspondence alone is not always practicable. Lecturers may be found and assigned readily enough, but the needs and wants of county societies and their experience with previous courses can only be ascertained by visits to the field. Arrangements for new courses, with suggestions for adequate publicity might well be made at the same time.

Our progress has been satisfactory. At the last meeting of the Council on Medical Education and Hospitals of the American Medical Association our plans were favorably received. A few county societies have not availed themselves of the opportunities offered them, while a few others, notably Kings and Queens, are carrying on graduate medical education without our assistance. The demand for new material comes from those counties where our activity has been greatest. As we cover the field, we look forward to elaboration of our plans.

Respectfully submitted,

March 15 1927

Nassau, Steuben and Tompkins, office orthopedics in Broome, cancer of the breast and empyema in Otsego, endocrinology, cancer of the breast, fractures, obstetrics and urology in Nassau

Dates have been definitely set for courses in pediatrics for Montgomery, Otsego and Schoharie, general medicine in Jefferson and St Lawrence, syphilis in Washington and Warren, and diseases of the heart and lungs in Columbia, possibly including Dutchess-Putnam

Arrangements are being made for courses in obstetrics or pediatrics for Allegany, Broome, Cayuga, Chenango, Montgomery, Oneida, and Tompkins, possibly including Livingston

Maps showing our detailed educational activities are incorporated in this report

Effort is now being made to stimulate in Albany, Buffalo, Rochester, Syracuse, Utica and Yonkers, a Practical Lectures Series such as has achieved phenomenal success in the counties of Kings and Queens

#### PUBLIC HEALTH

Our Committee has initiated and is guiding a diphtheria prevention campaign in the county of Schenectady. Their local Committee, organized with Dr Edwin MacD Stanton as

Chairman and Dr Howard A Gilmartin as Secretary, originated in the County Medical Society, but included representatives of the city and state health departments and civic and welfare organizations interested in public health

Their activity is based upon the following principles which we consider essential to the complete success of any plan for the betterment of public health

The medical profession is the one always present, all pervading, constantly active and always available medical force in any community. The county of state medical society, representing organized medicine, speaks for all the medical professions, whether they are a part of organized medicine or not

All public health movements, no matter how well organized, finally reach a point where progress is no longer possible without the assistance of the medical profession. We believe that this reflects not only the opinion of our Committee but the ideas of state and county departments of health and possibly voluntary health agencies as well

In the long run the real benefits of an individually applicable method such as the T-A procedure must be measured in terms of the benefits derived by the individual and those

in health examinations and may lead to the development of a State-wide policy

That (a) a Demonstration Clinic be instituted in a county preferably in an established physician's office, (b) with this as a teaching center all the members of a county society may be reached and at appointed hours may come in groups for a complete individual physical examination and a demonstration in the technique, system of records and follow-up course, (c) that after a period of possibly two months the demonstration may move on to another county, (d) that for a limited time the State Society provide funds to defray the expense of the demonstration, printed matter, the fee of the examiner and the nurse

Your committee recommends that the House of Delegates approve the establishment of a Demonstration Clinic in different parts of the State in order to determine the value of the plan. We also recommend that a course of instruction in physical examinations be added to the curriculum of schools of medicine in this State

While medical problems connected with Workmen's Compensation remain unsolved, nevertheless a movement has been initiated with a view of curbing the more flagrant impositions and abuses that have crept in

A Compensation Conference composed of heads of various insurance companies, a delegate from the Medical Society of the State of New York, a delegate from the State Society of Industrial Medicine and representatives of labor organizations, was formed in January as the result of a preliminary meeting called by the State Industrial Survey Commission

The Medical Society of the State of New York was invited to participate in the Preliminary meeting. President Fisher appointed Dr P H Hourigan, Chairman of the Special

Committee to Study Laws Affecting Workmen's Compensation and your Chairman of the Committee on Medical Economics, to attend the meeting in behalf of the State Medical Society

Meetings of the Conference will afford an opportunity to discuss and iron out some of the existing differences of the parties in interest and may be productive of much good

Your committee recommends that the House of Delegates approve the appointment of a representative from the State Medical Society to the Compensation Conference

Your committee has studied rural health problems, and has reviewed arguments for and against the establishment of County Health Units. Authority to establish a County Board of Health is vested by statute in the Board of Supervisors, subject to approval by the State Commissioner of Health

We recommend that when the creation of a County Health Unit is contemplated, the movement be initiated in the Medical Society of the County, and that the County Medical Society interest itself in securing constructive co-operation between its members, the State Commissioner of Health and the Board of Supervisors

Your committee finds the duties of officers of several County Medical Societies and District Branches are multiplying and require increased clerical assistance beyond the financial means of County Medical Societies. We suggest that each District Branch consider the advisability of employing a field secretary to execute detail work of component county societies of each district

Respectfully submitted,

W WARREN BRITT,

*Chairman*

March 15, 1927

## REPORT OF THE COMMITTEE ON SCIENTIFIC WORK

*To the House of Delegates*

Gentlemen

The Committee on Scientific Work takes pleasure in presenting the following report

The Committee has held two meetings—one in New York City and one in Utica, where the Committee was the guest of the President of the State Society

A glance at the program speaks for itself, as it shows the valuable subjects which will be discussed and the high type of the speakers

The Chairman extends to the Section Officers his sincere appreciation for the splendid cooperation which they have given him, to Dr Simpson for the valuable demonstration on Cancer which has been arranged under his chairmanship, and to Dr Fisher, President of the State Society, for his never failing interest in the work of the Committee

Respectfully submitted,

SAMUEL J KOPETZKY, *Chairman*

March 15, 1927

## REPORT OF THE COMMITTEE ON ARRANGEMENTS

*To the House of Delegates*

Gentlemen

Arrangements for holding the One Hundred and Twenty-first Annual Meeting of the Medical Society of the State of New York at Niagara Falls, May 9th to 12th, 1927, have been completed by the Committee on Arrangements as far as possible at this date

Meetings will be held in the Niagara Hotel, corner Jefferson Avenue and First Street, St Peter's Church, northwest corner of Jefferson Avenue and Second Street, Prospect House, northeast corner of Jefferson Avenue and Second Street, and K of C Home, Jefferson Avenue at the head of Second Street, opposite the Prospect House. It will thus be observed that all of the meeting places are on Jefferson Avenue within a radius of one block. The commercial exhibits will be in the Prospect House.

The Delegates' Dinner will be held at the Niagara Hotel on Monday evening, May 9th.

The Annual Banquet and Ball will be held on Tuesday evening, May 10th at 7 00 P M, in the ballroom of the Niagara Hotel. A dance will follow. The price will be six dollars per person, including the dance.

The Annual Meeting will be held Wednesday evening, May 11th, at 8 15 P M, in the Chamber of Commerce Building Auditorium, situated at 43 West Falls Street.

The Committee on Arrangements trusts that the facilities provided for the meeting will prove suitable and convenient. It is certain that the places selected for the holding of the meetings are situated in a most charming part of the city, so that with the attendance upon the Scientific Sessions will go the enjoyment of a pleasing environment.

The Committee wishes to express its appreciation and thanks to the Rev Philip W Mosher, Rector of St Peter's Church, and to the Board of Trustees for the tender of the church rooms for meeting places, they definitely declining the Committee's offer of compensation therefor.

The appreciation and thanks of the Committee are also extended to Mr George L Bowe, Manager of the Convention Bureau of the Niagara Falls Chamber of Commerce, whose counsel and assistance have always been available to the Committee. Mr Bowe has offered the services of his office personnel to the Committee during Convention Week at the Registration and Information Desks, which offer the Committee has gratefully accepted.

Respectfully submitted,

FREDERICK J SCHNELL, *Chairman*

March 15, 1927

## REPORT OF COMMITTEE ON MEDICAL ECONOMICS

*To the House of Delegates*

Gentlemen

The following Economic Problems have been studied the past year

1 Plans for making Periodic Health Examinations more practical for the general practitioner

2 Methods for the solution of medical problems connected with Workmen's Compensation

3 The relation of County Health Units to the welfare of the general practitioner

It is the opinion of your committee that Periodic Health Examinations of apparently healthy persons presents the single greatest step for the advancement of preventive medicine. The public is in process of being successfully educated to the value of this procedure for the assurance of better physical and mental health and the prolongation of useful lives.

One of the most pressing needs, your committee finds, is to arouse general practitioners to a keener realization of the wisdom and economic advantages of real physical examina-

tions, plus periodic re-examinations. Medical school training has not been along that line. Schools of medicine do not include health examinations in the curriculum, yet it is apparent that such examinations, for the most part, must be made by family physicians. The specialist only can help the general practitioner where his training and greater experience in his particular field make him especially proficient.

Many physicians feel themselves incompetent to make a health examination, and are loathe to undertake on a large scale a procedure that requires proper training, equipment and an intimate knowledge of systematic processes. To arouse greater interest among general practitioners and to speed the day of preventative medicine we recommend that the State Society adopt a definite program.

To that end your committee suggests the establishment of a Demonstration Clinic conducted under the direct supervision of a County Medical Society. We submit for your consideration the following plan which we believe is practical and a means of stimulating interest

ing the poor. They say they "love nursing" but cannot afford to continue it.

Hospital heads complain of unreasonable housing demands for nurses' homes, of an overloaded curriculum, of the inflexibility of the State Department of Education.

Your committee sympathizes with the complaints of the public representing the patient whose needs offer the immediate and most important reason for this study. Your committee believes that the complaints of the doctors are only justified by individual experiences in contact with unusual atypical personalities that are occasionally met in all professions, even in the medical profession.

Your committee believes that the complaints of the nurses reflect the economic evolution of a group of workers sincerely trying to render the best possible social service. Our reports from large schools of nursing that their classes are well filled prompts us to ask why young women should enter a difficult and disappointing profession which their older sisters are leaving.

Criticism of a state department is always a fair game. We cannot believe that the Department of Education occupies unassailable ground with the smug complacency of frozen perfection. If it did it would be dead. We are sure that it is very much alive to the restless, changing order and would welcome active agitation of all these problems with a hope for progress. Nursing housing is an acutely painful subject to those who are constructing or adapting living quarters for the convenience and comfort of nurses, but there must be a remedy which can be found in good-natured conference. So also the much discussed curriculum, which like other curricula is so overloaded that it can only be followed superficially, if at all, should be discussed by a committee composed of physicians and nurses uniting in a common effort to propose a simplified constructive useful substitute—a long and difficult piece of work.

Your committee has asked for sample curricula from specialists and as only one has so far been submitted we have no justification for detailed discussion.

A study of the supply of nurses reveals no shortage for the state as a whole, an abundant supply for cities, and faults of distribution seriously affecting rural districts. It would seem that no artifice could be devised to correct this condition, fifty-seven per cent of our people are urban and the population will continue to flow to and from towns following purely economic leads. Strategically placed hospitals and good roads would seem to be the only relief available for the rural counties.

A census of nurses and the distribution of nurses' services dated January 12, 1927, is divided into classes as follows:

Student Nurses, Private Duty, Institutional, Executive, Public Health, Industrial, School Nursing, District Visiting, Tuberculosis, Maternity.

Seventy-eight (78) per cent of the total are student nurses, private duty and district visiting nurses, all giving bedside nursing care. Outside of this census are a large number of nurses who have graduated from schools of nursing in other states and are not registered in the state of New York, who are carrying on their profession through commercial registries, private hospitals and so on, and the hundreds of so-called undergraduate and practical nurses who are giving some sort of nursing care. It is safe to estimate that there is at least one person to every two hundred (200) of the population of this state who is practicing with the title of nurse or attendant. There is no shortage of nurses in the large cities. The county of New York has one registered nurse to every 217 of its population.

The following table\* constructed from official records shows the number and distribution of nurses in New York State and the ratio of nurses to population.

Investigation seems to show that the nursing problem is concerned not so much with supply and demand as with distribution and economics. As one man said, there is no lack of nurses, but a lack of people who can afford to pay for their services. This does not mean that the registered nurse is overpaid, it means simply that the nursing service provided does not meet the nursing needs of the patient. While the doctors complain of a nursing shortage, the nurses say they are idle during a quarter of their time. There is evidently a lack of coordination somewhere.

In recent years the supply of bedside nurses has been decreased by the fact that many nurses go into special fields. Some nurses have also limited their services by selecting types of duty rather than being willing to work whenever and wherever called. Moreover, there has been a great deal of luxury nursing. A registered nurse is called for a mild case of illness or retained as a companion after the need has passed. She is called to care for children while the mother goes away. In the early days the bottle of medicine, not the nurse, cured the patient. Nowadays the appreciation of the personal care of the patient has increased and the physician orders a nurse without regard as to whether or not the patient is able to afford one. The family, anxious under the strain of illness, wishes to leave nothing undone that might make for the patient's comfort. Or perhaps the nurse is employed simply as a matter of social prestige. It is true now as in the past that the people who can afford servants can also afford nurses. It is largely the white collar man who for economic reasons is without a nurse and is complaining. Is some of the apparent

## REPORT OF THE SPECIAL COMMITTEE ON MEDICAL RESEARCH

*To the House of Delegates*

Gentlemen

On behalf of the Committee on Medical Research I beg leave to report as follows

The usual bill to prohibit experiments on living dogs, Assembly Int No 885, was introduced by Mr Vaughan and referred to the Committee on Codes. This Committee held a hearing on the bill on March 1st. Your Chairman was fortunate in having the State Commissioner of Health,

The Assistant Commissioner of Medical Education and Drs Graham Lusk, Horatio Williams and W Barclay Parsons present to ably defend the position of your Society in opposition to the proposed law. There is every reason to believe that it will not be enacted.

Respectfully submitted,

FREDERIC E. SONDERN, *Chairman*

March 15, 1927

## REPORT OF THE SPECIAL COMMITTEE TO STUDY THE NURSING PROBLEM

*To the House of Delegates*

Gentlemen

Your committee, appointed by the President to continue the study of the Nursing Problem, reports active investigation carried on by every member of the committee of the economic, educational and ethical development and relationship of the nursing service in the State of New York, and submits the following bill of complaints, statements of fact, arguments in support of suggested remedies, and recommendations.

The public, representing the patient, complains of unsatisfactory service in details of personal care and household adjustment, desires either the most highly trained and highly educated nurses, or some helpful persons of sufficient intelligence to carry out ordinary directions for the care and feeding of the invalided or sick in bed.

The patient complains that he is unable to pay the salary of the first group, plus food, and cannot discover a sufficient supply of the second group at prices within his means.

The patient who is sick in bed twenty-four hours a day reports that he must either be able to pay sixteen, or fourteen, or ten, or five dollars a day (plus food) for varying degrees of care or be hospitalized.

The patient who desires private nurses in private rooms in hospitals complains of being unable to avoid these maximum costs. A college professor recently reported his bill for private nurses in one of our large hospitals at \$17.00 per day, four dollars a day more than his income. The patient in the ward complains that he must go there with ten, twenty or forty others in order to be able to pay his way. The hospital cannot keep him through his convalescence and he returns to his home still needing nursing care that he cannot buy at a low enough price to be covered by the family budget.

Doctors complain that nurses are unwilling to serve every sort of patient, will not go to obstetrics, or contagion, or male patients, or babies, or night duty, or twenty-four hour duty, or by the month, or suburban patients, or go to the

country, or prepare and serve patients food, or keep the patient's room cleaned, or perform other comforting domestic service.

Doctors complain that some nurses are too highly educated to be nurses, are unwilling to follow the spirit or the letter of medical orders, substitute their own opinions for those already expressed by physicians, change or omit medication without seeking advice, assume undue responsibility, undertake diagnosis, treatment of minor cases, advise surgical measures, designate operators, and invade the field of the general practitioner.

Doctors complain that schools of nursing feed the nurses so much undigested theory and relegate so much practical work to servants that many nurses are quite unable to adjust themselves to homely conditions. One man says "Your high class nurse does not know how to poach an egg."

Nurses complain of over-much menial labor, of exhausting work, of long hours, of excessive extra-nursing demands, of irregular living, of loss of social opportunity, of seasonal occupation, of an average of eight months work out of a year, representing an average maximum wage, if they receive \$8.00 per day, of \$1,920 a year, that they reach this maximum immediately upon graduation, if ever, and experience a diminishing scale of average employment to a little past their fiftieth year of age, when they are worn out and have failed to provide a future for themselves through savings or pension.

Forty per cent of them are planning to leave private duty nursing to enter public health or industrial or institutional nursing or commercial life for three reasons: first, to secure regular yearly employment, second, an eight-hour day with regular vacations and Sundays and nights for rest and recreation, and third, a prospect of providing for sickness and old age. They express no regret at leaving the household service of the rich but only an acute sense of loss in their financial inability to enjoy the privilege of serv-

ing the poor. They say they "love nursing" but cannot afford to continue it.

Hospital heads complain of unreasonable housing demands for nurses' homes, of an overloaded curriculum, of the inflexibility of the State Department of Education.

Your committee sympathizes with the complaints of the public representing the patient whose needs offer the immediate and most important reason for this study. Your committee believes that the complaints of the doctors are only justified by individual experiences in contact with unusual atypical personalities that are occasionally met in all professions, even in the medical profession.

Your committee believes that the complaints of the nurses reflect the economic evolution of a group of workers sincerely trying to render the best possible social service. Our reports from large schools of nursing that their classes are well filled prompts us to ask why young women should enter a difficult and disappointing profession which their older sisters are leaving.

Criticism of a state department is always a fair game. We cannot believe that the Department of Education occupies unassailable ground with the smug complacency of frozen perfection. If it did it would be dead. We are sure that it is very much alive to the restless, changing order and would welcome active agitation of all these problems with a hope for progress. Nursing housing is an acutely painful subject to those who are constructing or adapting living quarters for the convenience and comfort of nurses, but there must be a remedy which can be found in good-natured conference. ## REPORT OF THE SPECIAL COMMITTEE TO STUDY THE NURSING PROBLEM

*To the House of Delegates*

Gentlemen

Your committee, appointed by the President to continue the study of the Nursing Problem, reports active investigation carried on by every member of the committee of the economic, educational and ethical development and relationship of the nursing service in the State of New York, and submits the following bill of complaints, statements of fact, arguments in support of suggested remedies, and recommendations.

The public, representing the patient, complains of unsatisfactory service in details of personal care and household adjustment, desires either the most highly trained and highly educated nurses, or some helpful persons of sufficient intelligence to carry out ordinary directions for the care and feeding of the invalided or sick in bed.

The patient complains that he is unable to pay the salary of the first group, plus food, and cannot discover a sufficient supply of the second group at prices within his means.

The patient who is sick in bed twenty-four hours a day reports that he must either be able to pay sixteen, or fourteen, or ten, or five dollars a day (plus food) for varying degrees of care or be hospitalized.

The patient who desires private nurses in private rooms in hospitals complains of being unable to avoid these maximum costs. A college professor recently reported his bill for private nurses in one of our large hospitals at \$17.00 per day, four dollars a day more than his income. The patient in the ward complains that he must go there with ten, twenty or forty others in order to be able to pay his way. The hospital cannot keep him through his convalescence and he returns to his home still needing nursing care that he cannot buy at a low enough price to be covered by the family budget.

Doctors complain that nurses are unwilling to serve every sort of patient, will not go to obstetrics, or contagion, or male patients, or babies, or night duty, or twenty-four hour duty, or by the month, or suburban patients, or go to the

country, or prepare and serve patients food, or keep the patient's room cleaned, or perform other comforting domestic service.

Doctors complain that some nurses are too highly educated to be nurses, are unwilling to follow the spirit or the letter of medical orders, substitute their own opinions for those already expressed by physicians, change or omit medication without seeking advice, assume undue responsibility, undertake diagnosis, treatment of minor cases, advise surgical measures, designate operators, and invade the field of the general practitioner.

Doctors complain that schools of nursing feed the nurses so much undigested theory and relegate so much practical work to servants that many nurses are quite unable to adjust themselves to homely conditions. One man says "Your high class nurse does not know how to poach an egg."

Nurses complain of over-much mental labor, of exhausting work, of long hours, of excessive extra-nursing demands, of irregular living, of loss of social opportunity, of seasonal occupation, of an average of eight months work out of a year, representing an average maximum wage, if they receive \$8.00 per day, of \$1,920 a year, that they reach this maximum immediately upon graduation, if ever, and experience a diminishing scale of average employment to a little past their fiftieth year of age, when they are worn out and have failed to provide a future for themselves through savings or pension.

Forty per cent of them are planning to leave private duty nursing to enter public health or industrial or institutional nursing or commercial life for three reasons: first, to secure regular yearly employment, second, an eight-hour day with regular vacations and Sundays and nights for rest and recreation, and third, a prospect of providing for sickness and old age. They express no regret at leaving the household service of the rich but only an acute sense of loss in their financial inability to enjoy the privilege of serv-

shortage due to the changing conditions of the past ten years which have so squeezed his salary that the cost of a nurse is practically prohibitive?

Hourly nursing offers a partial solution of the problem, a solution that has as yet hardly been tried except among the very poor. That paid hourly service at reasonable rates is professionally practical and socially respectable is an idea that doctors would do well to foster among their patients. By this means the patient is saved the salary of a full-time R. N. and the nurse is released for more necessary duties. Organized hourly nursing should prove most satisfactory also from the nurse's point of view, as it will provide her with more regular work at definite hours with regular pay and provision made for vacations and time off.

In connection with the extension of hourly nursing, we might do well to study the activities and practical operation of the visiting nurse associations. Hourly nursing is not at all a new idea, it has simply never been widely developed among the people who are able to pay. With the poorer classes this type of nursing service has been in successful operation for years and the mechanism for handling the work has already been developed and tested in actual practice. We are not suggesting that a new experiment be tried, but that the activities of a successful "going concern" should be enlarged or duplicated.

In the official registries in Buffalo and Brooklyn hourly nursing is now being offered and is utilized to some extent, but the public has not yet come to understand and appreciate the value of this kind of nursing and so it has been very little in demand. If the doctor will explain the hourly service to his patients and assist them to make use of it in suitable cases, the public will gradually become accustomed to the idea and take it as much for granted as they now do the 20-hour or 12-hour nurse.

A considerable part of the work of many visiting nurse associations is done in cooperation with insurance companies. Initiated by the Metropolitan Life Insurance Co. in 1909, this service has spread to almost every state in the union and has been attended by very satisfactory results on both sides, to the company and to the policyholder alike.

A very interesting report from the Utica Visiting Nurse Association shows the extent to which they work with the insurance companies as well as giving a very good general idea of their activities. During one year (Nov. 1, 1925 to Nov. 1, 1926), 69.2% of the 45,786 visits made by the Association were paid for by the insurance companies. Patients paid in full for 65% and in part for 31%. The remaining 21.2% of visits were made without charge.

Another possible factor in the solution of the question is some form of nursing aide. There

is a weight of evidence to support the opinion that a subsidiary nurse is greatly needed, though the trained attendants provided for by law in this state do not seem up to the present time to have supplied the need. One reason for this is that not enough women have taken the training as yet to make any appreciable difference. Evidently something must be done to make the field more attractive. The chief difficulty, however, is that the attendants in many cases practice independently after graduation at nurses' fees. This practice, of course, must be stopped. It has been suggested that the highest weekly rate for a trained attendant should be \$25.00. The most feasible means of regulating this and other matters is probably through central official registries.

And here is the most immediately practicable tool for attacking the whole problem, one which has already been successfully tried in Buffalo, Brooklyn and other places, and is now being used in Chicago. Here is a way by which all classes of nursing service may be honestly dispensed according to need. The registered nurse may find private duty, institutional or public service work, or hourly nursing, the nursing aide may be kept busy in the line for which she is really suited at a fee appropriate to her training, and undergraduates, graduates of unregistered schools and practical nurses all may be properly cared for. A bill has passed the Legislature in New York providing that nurses' registries shall give to the applicant and send to the employer a card stating the salary and qualifications of the applicant, thus safeguarding the public and the registered nurse against abuses arising from the demand for high salaries by unqualified persons.

The text of the amendment reads as follows:

"The term 'nurses' registry' means and includes the business of conducting any agency, bureau, office or other place for the purpose of procuring, offering, promising, or attempting to provide employment or engagements for nurses of any kind, or any place used as a lodging house for nurses, the keeper of which receives telephone calls or messages of any kind relative to the employment of such nurses and transmits such messages or calls to a nurse lodging in his or her house.

"Every nurses' registry that sends out any person to render nursing service shall give to each applicant and also send to the employer of such person within twenty-four hours of the time of employment a card stating the salary and qualifications of such applicant, also the name and place of the hospital and the length of time of service therein, or other experience in nursing if not in a hospital, and whether such person is a graduate, trained, certified, registered, undergraduate, or practical nurse, or trained attendant and if a graduate, trained, certified, or registered nurse or trained attendant, there shall also be

feel that too much education diverts the nurse's attention from the personal needs of the patient and causes her to usurp the doctor's prerogatives, but is this not a matter of the individual reaction of a particular nurse? Someone has said that nurses are not over-trained but over-educated. A better social adjustment might be promoted by a constant insistence throughout the course on teaching the art of nursing by demonstration, while less attention is paid to the purely didactic side. Those who do not favor a shorter course declare that the didactic content of a two years' or a three years' course is practically the same, but the extended period of actual bedside work is what makes the difference between a really good nurse and a merely ordinary one.

It is interesting to note that in 25 states a three years' course is required by law, and in three of these states—Maryland, Oregon and Utah—the student nurse must also have graduated from high school before she enters the training school. Three states require 28 or 30 months in training, and 18 require two years, while five state that the nurse must be a graduate of an approved training school. Twenty-one states require that the student nurse shall have had one year high school, 16 states two years, and five require high school graduation, while three states stipulate the completion of a grammar school course only, and six have even lower requirements.

There remains always the open question whether a subsidiary nurse can be or should be provided for the care of mild or chronic cases. It has been suggested that possibly the older nurses might care to undertake chronic cases at a smaller rate of pay in view of the more steady employment.

The nursing question would seem to be a perennial one. For years it has been studied by nurses' organizations and medical societies all over the country and all have reached much the same conclusions, but what has been done about it? The problem seems very little nearer solution than it was four years ago when the very stimulating report of the Rockefeller Committee was published. Very few experiments appear to have been tried even in directions that promised positive relief. The organization of any change in the present scheme of nursing service evident-

ly presents tremendous difficulties. But with the active and whole-hearted cooperation of doctors, nurses and hospitals the inevitable changes in the plan of private duty nursing can be worked out and the public can be educated to a more economic and economical use of the time of the registered nurse. It is for us to be pioneers in this work.

Your committee submits the following recommendations:

1 The establishment of official nurses' registries in every county of this state.

2 That every county society develop plans for the official approval of registries which meet satisfactory standards to be erected by the county society.

3 Sincere efforts toward co-ordination of all nursing services in each county.

4 Endorsement and encouragement of visiting nursing service.

5 Thorough trial by all of the members of the Medical Society of the State of New York of hourly or part-time nursing with broad publicity of its methods and possibilities.

6 Group nursing in hospitals.

7 That the period of training be twenty-eight (28) months, the first four months to be devoted to concentrated study of fundamental Anatomy, Bacteriology, Physiology, Chemistry and Dietetics, and that the succeeding two years be devoted as far as possible to teaching the art of nursing by demonstration, participation, and practice.

8 That a committee be formed to study the curriculum, the committee to be composed of three physicians, three nurses, and one representative of the Department of Education who shall be neither physician nor nurse.

Respectfully submitted,

## REPORT OF THE SPECIAL COMMITTEE TO STUDY LAWS AFFECTING WORKMEN'S COMPENSATION

*To the House of Delegates*

Gentlemen:

Your Special Committee to Study Laws Affecting Workmen's Compensation reports progress.

Primarily the work of your Committee during the past year has been of an educational

character. There are, however, certain tangible results which evidence a growing recognition of the Medical Profession by legislative and administrative governing bodies, which undoubtedly will lead to a better comprehension of all the problems involved unless the probable imminent benefits to the Profession are nullified by apathy and lack of understanding.

stated on such card the number of the annual registration certificate issued to such nurse or trained attendant by the regents of the University of the State of New York for the current year and a copy of such card left on file for reference in the agency

"In registering any graduate nurse or trained attendant such nurses' registry shall place on its file a statement showing the number and date of the last annual report of such nurse and trained attendant as shown by the annual registration certificate issued by the regents of the University of the State of New York. Such file records so kept by such nurses' registry shall be open to inspection by any authorized agent of the University of the State of New York and such agency shall submit the list in full upon request of such agent."

The bill is especially in the interest of the public which employs the nurse, but which now has no means of knowing the character of the stranger who comes to the bedside of the desperately sick, of the delicate child who needs tender care, and of the helpless invalid.

The bill is also in the interest of the doctor, who has assumed a responsibility in advising or insisting upon nursing care, and who will have some reasonable assurance by credentials that his directions will be faithfully carried out according to the ability of the certified person who will be sent from the certified registry. In fact the bill is a step toward officially controlled certified registries which may prove a most practical help in the solution of the nursing problem.

Moreover, an official registry under a competent, well-paid socially-minded nurse who knows from personal experience the details of nursing procedure, can do a very valuable work along the line of supervision. Nurses are almost the only group who go out from their preparation at the age of perhaps twenty-one and practice henceforth without any supervision and without being permanently responsible to any one. A properly organized central official registry might do much to improve the morale of the profession. Good nurses might be stimulated to retain their ambition, nurses deficient in certain lines might be encouraged to take special courses to round out their training, nurses who became careless in the performance of their duty might be discovered and warned. In no other way can such a high standard of service be maintained.

Another important way to increase the supply of nursing service is through group nursing in hospitals. This has already been successfully tried in some cases and where the experiments have not been successful the failure was not due to any inherent impracticability in the plan but in most cases to unreasoning prejudice. There is certainly no practical reason why one nurse should not care for three convalescent patients

in adjoining rooms, thus reducing the patient's charge and increasing the available supply of nurses by two. If the nurses, doctors, hospitals and patients will make an honest attempt to co-operate on this point, there is no question but what the result will be satisfactory to all concerned.

As nursing service becomes better distributed, the present supply of nurses will reach farther. What is true of the question of supply and demand today will not, we hope, continue to be true. Good nurses will always be said to be scarce, for they will always be the ones whose services are most in demand, but as long as nurses complain of a large amount of unemployment, it hardly seems possible that there can be any real widespread shortage except in times of unusual sickness. Employment in this field will always have a seasonal curve, but the same may be said of farming, building and even the practice of medicine.

Is it not the most important duty of this committee to make immediate efforts toward the better distribution of the nursing service already available? Let us repeat that no untried innovations are being urged. Hourly nursing has been proved feasible by the Visiting Nurse Associations. It is no more difficult to organize and district a city for privately paid visits than for free or contract ones. Let this work be extended to those who are able to pay for the amount of nursing they require but who cannot afford the full time of a registered nurse.

Group nursing has always been done in wards and one *student* nurse has been expected to care for five to eleven patients. Surely a *graduate* ought to be able to care for three in adjoining rooms. Or must the patient choose between a ward bed and a private room with two special nurses? Is there to be no other alternative?

The chairman has submitted the following definition of a basic nurse to be trained in two years which has met with wide approval.

"The basic nurse is a graduate who has completed a general hospital training school course in the theory, practice and art of nursing in two years, is fitted to nurse patients either in a hospital or at home, and is eligible for the degree of Registered Nurse."

But if there is no general shortage of nurses, is there any point in recommending for the registered nurse a course of training shorter than 28 months? Various doctors who have been questioned on the subject recommend periods of training ranging from eight months to three years, with a majority favoring the 28 months' course already adopted in several states. Many instances can be cited to prove that the number of applicants increases not as the standards are lowered but as they are raised. The quality of course is improved. It is true that some doctors

expected to function efficiently and become an instrument for good mainly through the force of public opinion backed by the ethics of the Medical Profession. Your Committee still believes that the plan is workable, that it is entirely devoid of political aspect, that it constitutes an obvious assumption of a patriotic obligation which belongs to the Medical Profession and that its greatest good will manifest itself in a humanitarian way for the benefit of those unfortunates for the relief of whom the statute was designed.

The problems presented by the Workmen's Compensation Law are continuing. The place occupied by the Medical Profession is still vague and uncertain. The importance of all of it is obvious. Your Committee commits the entire subject to your Honorable Body for such action as you may deem advisable and necessary.

Respectfully submitted,

H P HOURIGAN, *Chairman*

March 15, 1927

## REPORT OF COMMITTEE TO MAKE A STUDY OF HEART DISEASE

*To the House of Delegates*

Gentlemen

Herewith is submitted the preliminary report of the Committee "To Make a Study of Heart Disease."

Your Committee met for organization, preliminary discussion and planning on February 25, 1927, and April 1, 1927.

Two methods of attack have been planned, one to study mortality and the second to inquire into the morbidity.

The study of mortality will be made from the registered statistics in the office of the Department of Health, and from records of autopsies in hospitals. The mortality figures will include those filed according to the nomenclature of the International Causes of Death and numbered as follows:

- 51 Acute articular rheumatism
- 74 Cerebral hemorrhage and apoplexy
- 87 Pericarditis
- 88 Endocarditis and myocarditis—acute
- 89 Angina pectoris
- 90 Other diseases of the heart
- 91 Diseases of the arteries
- 92 Embolism and thrombosis
- 128 Nephritis
- 129 Brights

This information must be arranged to show by state, counties, cities and rural divisions, sex and age, studies of two samples of 1,000 certificates of a recent period and of a period ten or fifteen years before, to determine the trend of diagnosis. The autopsy records for a generous sample must be studied to learn the actual heart damage from the viewpoint of etiology.

To obtain information of morbidity, it will be necessary to make contact with many organized groups—military, hospital, school, college, industry and, if possible, pre-school, to demonstrate a continuous age incidence, from birth to death.

Preliminary inquiries of the State Department of Health, State Department of Education, State

Board of Charities, State Department of Labor, Division of Medical Charities of the State Board of Charities, State Department of Mental Hygiene, Metropolitan Life Insurance Company, New York State Society of Industrial Medicine, and Visiting Nurse Service of the Henry Street Settlement, have developed very cordial responses and promises of cooperation. The collection of the information will require considerable clerical assistance, as well as specially skilled statistical training and experience.

In order to purchase the statistical skill, the Committee recommends that the Trustees be requested to put at the disposal of the Committee, for the statistical compilation and study of the mortality records, a sum not to exceed \$2,000. For the employment of a statistician, skilled in hospital investigation and study of hospital records, who can make contact for the study of death certificates and autopsy records as made at the hospitals, a separate appropriation must be made. This will require a higher order of training and experience, as well as considerable travel to different hospitals in the State and it is requested that a sum, not to exceed \$5,000 be made available for this purpose.

In view of the great importance of the problem presented to the Committee, and the need of time to make contacts, collect, compile and correlate the information, it is requested that the Committee be continued and provided with the funds requested.

Respectfully submitted,

ROBERT H HALSEY, *Chairman*,

JOHN WYCKOFF, *Secretary*,

BERNARD S OPPENHEIMER,

HAROLD E B PARDEE,

LOUIS F BISHOP,

HERMON C GORDINIER,

EDWARD C REIFENSTEIN,

NELSON G RUSSELL,

WILLIAM H LOHMAN

March 15, 1927

Your Honorable Body will recall that the previous work of this Committee resulted in the presentation to the legislature of 1926 of what has come to be known as the Workmen's Compensation Procedure Act. This Act was introduced solely for the purpose of study and after a year of discussion and criticism your Committee is of the opinion that no better plan for the recognition of the Medical Profession has been devised, and we adhere to our recommendation of last year that the State Society officially endorse the measure and urge its passage by the legislature.

It is the opinion of your Committee that nowhere in our scheme of government is there a like opportunity for the Medical Profession to display a patriotic citizenship, that nowhere is there similar opportunity for the Profession to prove its willingness to assume the manifest obligation which a humanitarian law has put upon it, that never before has there been a time when patriotism and humanitarianism called so compellingly or with so much reason.

There is no intention on the part of your Committee to reiterate what it has said before or to rehash the happenings of the past year, notwithstanding that the year has adduced much that directly affects the Medical Profession, even within the limited scope of the work of this Committee. We have felt that the importance of workmen's compensation from the medical standpoint has been underestimated when it has not been ignored. Your Committee has consistently refused to contemplate the problem from the practical viewpoint, and has maintained an attitude which is believed to be consistent with the high ideals and ethics of the Profession. But during the past year the practical aspect has been emphasized to such a degree that your Committee feels it cannot further ignore it and that practicality must be considered as well as ideals.

The New York State Industrial Survey Commission, a legislative body, has made the most sweeping investigation of the subject of workmen's compensation with, however, negligent attention to the medical problems. Yet it is an outstanding fact as evidenced by the report of this Commission, that from the standpoint of sordid dollars and cents the ideals of the Medical Profession are affected to an extent that demands immediate attention. One of the astonishing things stressed by the report of the Survey Commission was that workmen's compensation in New York State alone involved an expenditure of more than sixty million dollars (\$60,000,000 00) annually, and that of this gigantic sum twenty-three (23) per cent was expended for medical costs. Ordinary arithmetic shows that this means that approximately fifteen million dollars (\$15,000,000 00) annually constitute the takings of the Medical

Profession and its allied interests. Where has this money gone? How was it expended? What has been the effect of the Compulsory Expenditure of that great sum upon the Profession? Your Committee cannot give you the answer. Yet your Committee believes that the compulsory expenditure of that sum of money puts upon the Medical Profession generally the duty of upholding and safeguarding the ideals which have been built up over the centuries and seeing to it that not the faintest breath of scandal results from this contact with Mammon.

The Industrial Survey Commission itself recognized that there was a danger involved. As one of the expedients for checking possible abuses that might arise under the administration of the workmen's compensation law, the Commission called together a conference calculated to include all parties in interest. For the first time, so far as your Committee has been able to ascertain, a legislative body officially recognized the Medical Profession and both the Medical Society of the State of New York and the New York State Society of Industrial Medicine were represented. As a result of that preliminary conference a permanent body was set up, to be known as the "Workmen's Compensation Conference," and two doctors were given places on the Board—the Chairman of the Committee on Economics of the State Society, Dr. W. Warren Britt, and the Chairman of your Special Committee which makes this report. At the time of writing this report the "Workmen's Compensation Conference" has held but one meeting, an organization meeting, at which Henry D. Dayer, a former industrial commissioner and executive secretary of the Survey Commission, was made chairman.

These things are touched upon merely as indicative of the trend. Yet your Committee believes that even such slight gains as these will be nullified if the State Society decides upon or continues a negative policy in connection with this great subject.

As a practical solution of this problem your Committee stands upon its report to your Honorable Body of last year. We recommended that the Society endorse by adoption the plan laid down in the proposed Workmen's Compensation Medical Procedure Act. That Act was permissive in all its organization detail and mandatory only wherein it related to these special administrative details that bade fair to bring the Profession into disrepute, such as conflicts of medical testimony and kindred subjects.

The State Medical Advisory Council and the District Medical Advisory Councils were just what the names implied—advisory bodies without definite administrative powers which were

should be presented to the legislative committee, so far as possible, from the point of view of the public health by those officially charged with its protection. Following out this program, the witnesses who gave personal evidence before the committee consisted of Dr Matthias Nicoll, the State Commissioner of Health, Dr Louis I Harris, Commissioner of Health for New York City, Dr Augustus S Downing, Assistant Commissioner and Director of Professional Education; Dr Harold Rypins, Secretary of the State Board of Medical Examiners, Dr Frederick Parsons, Commissioner of the State Department of Mental Hygiene, Dr William D Cutter, Dean of the Post Graduate Medical School (former Secretary of the State Board of Medical Examiners), and Mr George J Nelbach, Executive Secretary of the State Charities Aid Association. These gentlemen, so well qualified to express authoritative opinions, gave testimony to the effect that the licensing to practice any phase of medicine by those whose educational qualifications were far below the standards of the State Department of Education, and whose lack of knowledge prevented them from making a proper diagnosis and therefore of carrying on a proper treatment, would be a serious, fundamental and dangerous jeopardy to the health of our people. In the most direct and unequivocal fashion these gentlemen testified that there was no need for further legislation and that they were unalterably opposed to any law looking to the licensing of chiropractors which directly or indirectly failed to require that they possess the educational qualifications now in force for the practice of medicine. Supplementing this testimony evidence was likewise given by Dr James E Sadler, president-elect of your society, and Dr James F. Rooney, a past-president of your society. And there was likewise offered and introduced in evidence a report of upwards of two hundred and fifty pages on the subject of chiropractic prepared pursuant to a resolution of the New York County Medical Society, which report was compiled by your former counsel, Mr George W Whiteside, and your attorney, Mr Robert Oliver. The report consisted of an analysis of chiropractic textbooks and of answers to hypothetical questions as to the therapeutic value of chiropractic propounded to Dr N E Brill, Dr Charles H Chetwood, Dr John A Fordyce, Dr Isidore Friesner, Dr V P Gibney, Dr Arnold Knapp, Dr William H Park, Dr Charles H Peck, Dr Wendell C Phillips, Dr A J Rongy, Dr Reginald H Sayre, Dr Royal Whitman and Dr Charles A Elsberg. The hypothetical question propounded to these eminent physicians contained an analysis of the teachings of chiropractic and sought an opinion of its scientific or therapeutic value. Each of these distinguished men, in response to that hypothetical question, unqualifiedly condemned chiropractic as unsound. This

opinion was not only presented and received in its entirety, but Mr Robert Oliver testified as a witness in explanation of the report, giving an analysis of its contents, of its character and of its findings. In addition to all this there was the testimony of Mrs Sarah M Ahern, a patrol-woman of the Police Department of the City of New York, who was assigned to the office of the District Attorney of New York County to investigate violations of the Medical Practice Act. She testified to having visited a number of chiropractors and of having been diagnosed as suffering from numerous ailments when in fact she was in perfect health.

At the conclusion of the hearings a memorandum of law was prepared by your counsel and submitted to the committee showing that the practice of chiropractic constituted "the practice of medicine" within the meaning of the Public Health Law, and further that the Medical Practice Act of 1926 did not change the definition of the practice of medicine which has been in force for twenty years.

#### COUNSEL WORK

During the period of this report your counsel has prepared for publication in the society's journal articles in the nature of editorial comment. The editorials have included the following:

The Chiropractor and the Drugless Practitioner  
The Proposed Medical Practice Act of 1926  
The Germ Theory and the Chiropractor—A New Judicial Revelation of the Charlatan  
Individualism—Its Merits and Its Dangers  
Character the Real Basis of Professional Confidence.  
The Webb-Loomis Bill Becomes a Law  
The Doctor Carries On.  
The Doctor as a Citizen.  
The Doctor and the Will  
The Year's Work Begins  
The Art of Giving Testimony  
Disciplinary Powers and Functions of the State and County Societies  
Criticism of Physicians by Physicians  
The Supreme Court of the United States Limits the Practice of Medicine.  
Let Us Face the New Year with Unity and Concord.  
The Grievance Committee Gets Under Way  
Arbitration One of the Most Important Powers Vested in the New Committee on Grievances

As in the past, counsel has digested, and there has been published in the JOURNAL, reports upon malpractice actions which have been disposed of by your counsel. The case reports published during the previous year are as follows:

Pregnancy—Pylitis Subsequent to Delivery and Resultant Hysterectomy  
Claimed Diagnosis of Gall Stones Instead of Appendicitis.  
Action for Services Rendered—Malpractice Counter-claim.  
Fractured Elbow—Impairment of Function  
Laceration of Hand and Infection of Hand and Fore-arm.  
Tonsillectomy—Local Anaesthesia—Breaking of Needle.  
Infection of Finger  
Failure to Remove Stone in Operation upon Gall Bladder

## REPORT OF COUNSEL FROM FEBRUARY 1, 1926 TO FEBRUARY 28, 1927

*To the House of Delegates*

Gentlemen

Counsel herewith submits his report for the period of thirteen months beginning February 1, 1926, and ending February 28, 1927

This is the writer's first full year as counsel of your society. It has been a full year in more ways than one. The past thirteen months have given him an opportunity to gain a keener insight into the manifold problems with which the medical profession always is confronted. As he has gone about his various duties, in conference with your officers, committees, representatives and individual members, as he has appeared for you before individual county societies, before your board of censors, executive committee, the council, in trial and appellate courts, in legislative halls and in the executive chamber, he has been impressed by the high standards and fine ideals of your profession and has been encouraged to put forth the best he had in furtherance of its worthy aims. Not only has he been given opportunity to observe and study the problems of the profession as a whole, but the problems which confront many individual practitioners in their daily work. Your counsel cannot fail to express here at the beginning his appreciation and gratitude for the kindness, good-will and the loyal cooperation which have been accorded him by the profession generally and also by its individual members, with many of whom strong ties of personal friendship have been formed by reason of the multifarious duties which have devolved upon him and his frequent opportunity to champion the cause of medicine in general and the good name and professional standing of individuals before courts and juries.

The work of the year divides itself into three main divisions: first, the legislative activities, second, counsel's work with the officers, committees and individual members of the society, and third, the actual handling of malpractice actions before courts and juries and in the appellate tribunals.

#### LEGISLATION

In the legislative field the past thirteen months have witnessed the consummation of the most constructive effort ever perhaps attempted by your or any other medical society,—the enactment of the Medical Practice Act of 1926. This progressive law, with the terms of which all of you are so familiar and concerning which your counsel has spoken and written so fully, is looked upon throughout many of the states of the Union and in Canada as a standard and a model for progressive public health and medical legislation. Too much credit cannot be accorded to your officers and committees who took the laboring oar

in the formulation and promulgation of this statute.

In connection with this legislation your counsel attended meetings and conferences of committees and officers of the State Society and representatives of the state departments and other public officials, and appeared on several occasions before the legislative committees and before the Governor, presenting arguments on behalf of the medical profession in support of the passage of the Medical Practice Act, and rebutting the contentions of the chiropractors and other cultists who did all within their power to defeat this remedial legislation. Your counsel likewise opposed the passage of the various chiropractic bills by presenting the reasons why such legislation would be detrimental to the health and general welfare of the people of this State and why their ill-considered bills should not find a place on our statute books.

From time to time during the past and present legislative sessions your counsel has received from Chairman Dr. Henry L. K. Shaw and his efficient legislative committee, bills introduced in the legislature affecting the medical profession or seeking rights or recognition on behalf of the various faddists, cultists and other enemies of the public health. An enumeration of some of these proposals would form a valuable contribution to any anthology or analysis of wit and humor were it not for the fact that such measures carry an element of tragic warning to the honorable practitioners of the healing art as to the extent active groups within this State are seeking, for their own selfish gain, to undermine the medical profession and endanger the health of our people by playing upon human credulity or ignorance. These various measures have been analyzed by your counsel and he has expressed his views and rendered his opinions upon the legal phases that were involved.

At the last session of the Legislature a resolution was adopted providing for the appointment of a joint committee of the Assembly and the Senate to investigate and inquire into the practice of chiropractic. Until the latter part of December, 1926, no steps were taken by this committee to function under the resolution. On December 22 and 23, 1926, hearings were had by the committee at which the chiropractors introduced evidence. The next meeting was had on January 27, 1927. Hearings were then had on February 3rd at Albany and on February 4th at New York City, at which the opponents of chiropractic introduced evidence. At the various conferences with the representatives of the society and at the hearings, your counsel or attorney attended and participated therein. A well considered program or course of action was devised and carried out. It was decided that the question

of the meetings of the Council and Executive Committee during the year

From time to time the Executive Committee and the officers of your society have sought the advice of counsel upon various subjects and matters pertaining to the society's business. Your counsel has had occasion to advise the Council, Executive Committee and the officers of your society, among other questions, upon the following

Whether or not the names of the living ex-Presidents of the state association should be included in a published list of the living ex-Presidents of the society  
Advice as to the response to be made to a communication from a county society

Preparation and advice in connection therewith of a questionnaire of the American Medical Association with reference to malpractice defense.

Advice and opinion upon the duty of a suspended member to pay dues or assessments during the period of suspension

Advice concerning the powers of the Council to adopt a resolution of censure of the action of a county society

Advice and opinion upon the rights of physicians charged with violation of the Harrison Narcotic Law

Advice as to the action of the Executive Committee with reference to the publication in the JOURNAL of resolutions of a county society

Advice and opinion as to the right of the Department of Internal Revenue to compromise claims and the effect of such compromise upon a physician's license.

In this matter your counsel made an extended review of the facts in the matter, the Harrison Narcotic Law, the regulations promulgated by the Department of Internal Revenue and the decisions of the United States Supreme Court adjudicating upon various provisions of the Harrison Narcotic Law as the same applies to the physician and prepared and rendered to the Executive Committee a written opinion including the results of the research on the subject

Your counsel attended the Annual Meeting of the Homeopathic Medical Society and made an address upon the Legal Hazards of the Practice of Medicine

Your counsel also attended a meeting of the Bronx County Medical Society and addressed said meeting on the Medical Practice Act of 1926

Your attorney was a guest at another meeting of the Bronx County Medical Society and spoke to the members at that meeting on the subject of the practice of medicine from a legal viewpoint.

Your counsel and your attorney also attended meetings of the Society of Medical Jurisprudence and discussed the liability of the roentgenologist and the control of cosmetics

Your counsel also attended and addressed the meeting of the Bay Ridge Medical Society

#### BY-LAWS

Your counsel received communications from the Executive Committee with reference to the amendment of the by-laws of the Erie County So-

ciety and examined the proposed amendments thereto and gave an opinion with reference to such amendments

Your counsel also received communications from and advised the Cortland County Society as to various powers and rights under its by-laws

Amendments to the by-laws of the Oneida County Society were also examined and passed upon by your counsel, likewise proposed amendments to the constitution and by-laws of Queens and Bronx County societies were the subject of examination and opinion to these societies by your counsel

#### BOARD OF CENSORS

During the year appeals in two matters have been had from county societies to the Board of Censors

An appeal was had by one Dr Benjamin from the action of the New York County Society in refusing to admit said Benjamin to membership. On this appeal a hearing was had before the Board of Censors. Witnesses were examined and cross-examined and the proceedings were stenographically reported and transcribed. The matter of the appeal was then examined by your counsel and advice and an opinion given to the Board of Censors with reference thereto. In connection with this matter your counsel also had correspondence with your officers and with the attorney for the appellant and he likewise made an examination and digest of law with reference to the rights of an applicant for admission to membership in a medical society

In the matter of Dr C Everett Field an appeal was taken from the action of expulsion by the Queens County Society. In this matter a hearing was had before the Board of Censors and the appellant and his attorney heard on the appeal. The appellant and his witnesses were examined by your counsel. The minutes of this hearing were stenographically reported and transcribed, which minutes, together with the various exhibits—which were rather voluminous—were examined by your counsel. A conference was had with the Board of Censors and advice given by your counsel in the matter. Your counsel also prepared for the Board of Censors an opinion and judgment in this appeal

#### LITIGATION

The work performed by your counsel which affects the individual practitioner most directly falls under the head of litigation. It is a matter of importance to every doctor that sound laws should be sponsored and unsound legislation opposed, that the unlawful operations of cultists and faddists should be prevented and that the dignity and high standing of the medical profession should be upheld, it is a matter of importance to the individual practitioner that the affairs

Delay in Diagnosis of a Fracture  
 Diagnosis of Stone in Urinary Bladder and Prostate  
 Gland Enlargement  
 Bronchial Pneumonia—Resolving Otitis Media  
 Encephalitis  
 Third Degree Burns or Tropic Ulcers  
 Fibro-Sarcoma—Roentgen Reaction.  
 Collection of Bill—Malpractice Counterclaim.  
 Mastoiditis Complicated by Otitis Media and Tonsillitis  
 Followed by Death from Endocarditis  
 Hypodermic Injection—Broken Needle.  
 Claimed Burn from Therapeutic Lamp  
 Sinusitis—Brain Abscess  
 Tonsillectomy—Hemorrhage.  
 Tonsillectomy—Lung Abscess  
 Mastoiditis Following Influenza—Collection of Bill—  
 Counterclaim  
 Laceration of Thumb Followed by Infection Resulting  
 in Loss of Function of Hand  
 Claimed Improper Treatment of Infection of Face and  
 Eye.  
 Inguinal Hernia—Subsequent Femoral Hernia  
 Fractured Femur—Slight Overriding—Callus Forma-  
 tion—Subsequent Open Operation and Lane Plating  
 Fracture of the Elbow—Workmen's Compensation.

The editorials and case reports thus prepared for publication in the JOURNAL by your counsel covered from two to six pages in each of the issues of the JOURNAL and consisted of about sixty pages of printed matter or approximately fifty-five thousand words. The preparation of the editorials required a considerable amount of time and necessitated research into the facts and the law of the subjects written upon. Likewise the digesting and reporting of the cases previously disposed of required a careful review of the facts in each case and a careful preparation of the digest.

Inquiries from various sources for advice and opinions upon various subjects are being constantly received by your counsel. These inquiries come from county societies, officers or committees of such societies, members of the society in various parts of the State, associations allied to or interested in medical subjects and from lay persons seeking information upon medical or medico-legal matters. These inquiries are made by personal calls, telephone calls and correspondence. Some of the inquiries which have been a matter of correspondence are as follows:

Communication as to a member's right to defense and coverage under the group plan of insurance  
 Communication relative to Chiropractic-Naturopathic Protective Association.  
 Inquiry with reference to the right of a physician to disclose information received by him in the course of treatment of a patient.  
 Inquiry with reference to the status and standing of a physician.  
 Inquiry requesting advice in a malpractice action and of the law governing the liability of the physician therein.  
 Inquiry with reference to the matter of the Health Commissioner furnishing lists of newly-born legitimate children to a milk commission.  
 Inquiry seeking information as to the source of obtaining a serum for the cure of high blood pressure.  
 Inquiry as to the length of time roentgenologists are required to keep X-ray films  
 Request for advice from a clinic as to the right of the

clinic to give information to charitable organizations of the results of Wassermann tests of its patients  
 Communication with reference to the statute requirements of registering still-born children and advice thereon  
 Inquiry as to the liability of the medical board of a hospital in a malpractice action instituted by a patient receiving treatment at its free ward.  
 Inquiry and advice as to the right of a physician to exhibit at medical meetings motion pictures of a patient.  
 Inquiry and advice as to the Statute of Limitations governing actions of malpractice  
 Communication requesting advice as to the rights of a physician to collect for services rendered in an emergency  
 Communication and advice as to the rights of a physician under the group plan of insurance.  
 Communication from a physician as to his rights to receive payment of a bill rendered to the State Insurance Fund for treatment of a Workmen's Compensation case.  
 Request for information as to the status of the Union Gospel Mission  
 Advice to a physician as to the effect of receiving a reduced amount of his bill in full payment of the same.  
 Inquiry and advice to a physician with reference to the license fee of the Internal Revenue Department for narcotic drug license  
 Inquiry and advice as to the right of a physician to defense who is charged with violation of the Harrison Narcotic Law  
 Communication with reference to the illegal practice of medicine by a physician  
 Advice to a physician as to the confidential relation existing between physician and patient.  
 Communication from a county society as to the medical operations of an industrial plant.  
 Communication requesting advice as the medical practice act of Texas  
 Communication from a physician requesting advice as to the confidential relation existing between a physician and patient  
 Communication and advice on what is the legal basis in the United States indicating that a child is born alive  
 Inquiry from a physician as to his rights to defense and coverage who is charged with violation of the Harrison Narcotic Law  
 Communication from superintendent of a sanitarium as to the liability of such sanitarium for injury to a patient and advice thereon.  
 Communication as to the jurisdiction and authority of county societies to discipline its members  
 Communication from a county society as to the right of the society to proceed against a member for violation of medical ethics  
 Communication from a physician with reference to the presentation of his bill before the State Industrial Commission and the refusal of the Commission to honor the same  
 Communication and advice from a physician as to his legal right to engage an assistant to care for his practice during his absence in Europe, which assistant was a graduate physician of a foreign university but unlicensed in this State.

All the preceding inquiries and communications required considerable investigation and frequently involved the giving of legal opinions and careful analysis and interpretation of legal questions.

Your counsel and attorney both personally attended the last Annual Meeting of the society and either your counsel or attorney attended at each

years after the services have been rendered. An action for malpractice is barred after two years from the date on which the cause of action arose. Where physicians have brought actions for services within two years, they frequently have been confronted with a counterclaim charging malpractice, and which action is not yet barred by the Statute of Limitations. Frequently these counterclaims represent a mere expression of ingratitude and an attempt to defeat the just claim for services. Whatever the motive underlying the counterclaim may be, the effect of the counterclaim is to inject the doctor into a malpractice suit which must be defended.

Table I, which follows, is a summary of the number of suits instituted and disposed of during the period reported on.

TABLE I

Number of Suits Instituted and Disposed of

	Instituted 1926 1927	Disposed of 1926 1927
1 Fractures, etc.	15	12
2 Obstetrics, etc.	22	26
3 Amputations	1	1
4 Burns, X-ray, etc.	15	14
5 Operations—abdominal, eye, tonsil, ear, etc.	33	33
6 Needles breaking	3	2
7 Infections	10	7
8 Eye infections	4	5
9 Diagnosis	14	8
10 Lunacy commitments	3	2

Actions for death	13	11
Infants' actions	13	8
	26	19
How DISPOSED OF		
Settled		25
Dismissed, discontinued, abated or tried (verdict for defendant)		112
Judgment for plaintiff		6
Appeals (judgment for defendant)		3
Totals	166	146
Pending on February 28, 1927	375	

An analysis of the foregoing table shows that the number of malpractice actions instituted is ever on the increase, that during the period reported on, 34 more suits were instituted than during the period reported on in the last Annual Report. The number of suits instituted during this period is 20 in excess of the number of suits disposed of and therefore adds that number of cases to those now pending disposition.

Even those who have been defendants in malpractice actions probably do not fully realize all the work that is entailed in the handling of one of these cases. In every case a statement, not only of the defendant doctor, but of each wit-

ness having knowledge of the facts is secured. Experts are interviewed. A research into the medicine is made. There is an examination of the particular legal authorities bearing on the question. All of this work entails repeated conferences and a consistent study and application, much of which effort is never seen by the doctor but is reflected in the results which are secured.

Your counsel cannot speak too highly of the splendid assistance and loyal cooperation that is constantly accorded to him by Mr. Robert Oliver, your attorney, whose knowledge and experience with this type of cases is literally invaluable.

In addition to Mr. Oliver your counsel has in his office two other able lawyers—Mr. Lorenz J. Brosnan and Mr. Maxwell C. Klatt, both of whom devote the major part of their time to work of the physicians.

Mr. Brosnan has been associated with your counsel and with the predecessor firm of White-side & Stryker for upwards of seven years and has assisted your counsel in the trial of many cases.

Credit should also be given to the other employees of counsel's office, all of whom have become familiar with the work and who have rendered their loyal and enthusiastic cooperation.

Table II which follows, is a comparison of the members insured in 1925 and 1926 with those of 1927.

The figures speak for themselves, but it is a satisfaction to note that the number of insured doctors has increased 3 per cent. during the past year, that is to say, 6073 members are now insured as compared with 5711 in the preceding year. In nearly all of the larger counties an increasing appreciation of the group plan is displayed by the larger number availing themselves of its benefits. Thus, for example, in Kings County there are now 57 per cent of the doctors insured as compared with 52 per cent. for the preceding year or a total number of 933 insured members as compared with 831,—an increase of 102. In New York County 59 per cent of the doctors are now insured as compared with 57 per cent for the preceding year or a total number of 2069 as compared with 1961,—an increase of 108. In Queens County 58 per cent of the doctors are now insured as compared with 54 per cent for the preceding year or a total number of 194 as compared with 146,—an increase of 48. In Westchester County there has been an increase of 6 per cent. In Bronx County there has been an increase of 2 per cent. Decreases are noted in a few of the counties, notable among which is Montgomery County with a decrease of 18 per cent. Albany County shows a decrease of 3 per cent.

Your counsel repeats what he has so often said both privately and in editorials. *The group plan is working well.* The plan is one which deserves and has received the increasing support and ap-

of his society should be well and efficiently conducted under sound and constructive advice. But there is nothing more important to the individual physician than the protection of his good name, reputation and the fruits of his labor. A malpractice action strikes a body blow at all that the doctor has spent his life in building up—his good name, his reputation and the accumulation of his professional earnings. By such an assault not only is the doctor personally attacked, but through him the welfare and happiness of his family.

Through frequent editorials, addresses at medical meetings and in private conferences, your counsel has sounded the warning and has called attention to the dangerous trend of the times. Your counsel in his last Annual Report declared

"Perhaps it might not be out of place here to notice how fortunate the doctors have been thus far in avoiding large verdicts. The trend of the times in every other field of negligence law is unquestionably toward larger damages where juries find in favor of the plaintiff. The present value of the dollar is always taken into consideration, so that it is safe to say where a jury ten years ago might have rendered a verdict for ten thousand dollars, it will now award double that sum or more. Juries have become increasingly liberal with the money of defendants in every other field of negligence cases when they find against them."

What is the reason for this trend? Undoubtedly there are many reasons. Among these might be cited the fact that through the medium of workmen's compensation laws a large field of negligence litigation has now been cut off. That class of lawyers who formerly spent much of their time in bringing damage suits on behalf of injured workmen against their employers, have cast about for other avenues of revenue and in their search have come to the conclusion that the ingratitude or avarice of patients could be crystallized into malpractice actions against the physicians who have treated them and that this offered a new opportunity in the negligence field.

Then, too, there has been of recent years a signal growth in the ranks of specialists. These men do not come into such personal and close relations with their patients as did the old family practitioner, thereby losing perhaps some of the personal regard which patients of a former generation entertained for the old-fashioned general practitioner. Unquestionably the actual benefit which these old-time doctors performed for their patients was not of as great scientific value as the more highly specialized services that now are rendered, yet the old doctors, of whom Oliver Wendell Holmes so beautifully has written, acquired a hold upon the affections and the regard of their patients which usually prevented the patient from assailing the physician who had done all within his power to help him.

Again, where specialists are engaged and paid on the basis of their exceptional knowledge, more of skill advice is required of them by the

courts and more is expected of them by the patient. Thus where heretofore judges have been charging juries, under the rule of *Pike against Housinger*, that a doctor is required to possess and exercise that "degree of learning and skill that is ordinarily possessed by physicians and surgeons in the locality where he practices," now, where specialists are sued, the judges universally charge their juries that it is not enough for the specialist to possess and exercise the knowledge and skill of the average physician, but that he must possess and exercise that degree of skill and learning which a specialist in his particular field should possess and exercise.

Furthermore, in some of the cases specialists have been charged with failing to accord the necessary after-care. The failure to render after-care and to make visits at the patient's home often (whether justified or not) arouses the anger of the patient or his family and has been the basis of malpractice actions. Of the six cases tried during the past year in which verdicts for the plaintiffs have been rendered, two were based upon the failure of the defendant specialist to render the necessary post-operative care.

And these very things have been the basis of the twenty-five settlements which were effected during the period of this report. In this connection it should be said that none of the settlements made were effected without the full consent, acquiescence and approval, and in many instances at the urgent request of the physician sued. Before any of these settlements were recommended or made, an exhaustive study of the facts, the medicine and the law in each particular case was scrupulously made, as a result of which your counsel was convinced that the best interests of the physician would be served by the consummation of the settlement effected. The policy of the State Society and of its individual members never to make a settlement for mere nuisance value—never to effect a compromise unless the evidence of liability is clear and overwhelming, has been sedulously followed and adhered to.

In addition to all of the foregoing reasons, two others should be cited—the increasing use of mechanical appliances and the counterclaim actions which arise in response to physicians' suits for services.

The increasing use of mechanical appliances is a fact well recognized by the medical profession. In the various fields of diagnosis and especially in the field of rehabilitation of industrial injuries, mechanical devices increasingly are used. Among these appliances might be mentioned quartz and alpine lamps, bakers of various types and other forms of electrical-therapeutic apparatus.

Many physicians feeling justly aggrieved at the non-payment of their fees, have brought actions for their services. An action for professional services may be brought at any time within six

induce those not insured to join in our group plan of insurance."

Table III is a schedule of premiums for insurance. It is the same as last year and therefore requires no comment.

It is a pleasure to record our thanks for the understanding, cooperation, advice and assistance which your counsel has received from your various officers and committees. The results secured could not have been obtained without the loyal good-will and support of which your counsel has been at all times the fortunate recipient. Doctors have come forward with medical advice and testimony in support of their brethren in the profession and the opinions which they have rendered to your counsel, both privately and in court, have been of the highest scientific value and of great persuasive force before courts and juries and have largely contributed to all of the satisfactory results which have been obtained in the disposition of cases.

To Mr Harry F Wanvig, representative of your society under the Group Liability Plan, in large measure is due the increase in the number of policies which have been written, particularly within his own district. Constant questions arise in regard to insurance matters and he at all times has displayed a cordial willingness to give of his time and advice to your members. Likewise he

has appeared from time to time before various medical society meetings and has explained the nature of the group plan and its benefits to them. The further success of the group plan depends upon the continued cooperation not only of your society, but of its individual members. Your counsel feels that Mr Wanvig is well deserving of your continued support and confidence as your society's designated representative.

Counsel has been thrown frequently in contact with the officers and representatives of your insurance carrier and has received from them loyal and sympathetic cooperation, with a willingness to assist the doctors in their respective territories. The volume of business now carried on could not be satisfactorily administered throughout the various counties of the State without the assistance and cooperation of these representatives in the writing of insurance, in the assembling of facts and assistance in the preparation of the cases down to the point of trial.

While we should not be blinded to the difficulties and the problems which confront us, it is believed that there is every reason for facing the new year with confidence and optimism.

LLOYD PAUL STRYKER,

March 1, 1927

Counsel

## REPORT OF THE COUNCILLOR OF THE FIRST DISTRICT BRANCH

To the House of Delegates  
Gentlemen

As President of the First District Branch of the Medical Society of the State of New York, I respectfully report as follows:

In the beginning I wish to say that by reason of stress of business it has been impossible for me to attend the meetings of the various

Societies in the First District, with the exception of two, outside of my own County Society, but I have been in touch with the entire District and I feel that the First District Branch is going ahead in a satisfactory manner.

The annual meeting was held at Briarcliffe Lodge, Briarcliffe Manor, New York, on the

preciation of your members In this connection the resolution adopted at the last meeting of the House of Delegates is worthy of reiteration

"Your Committee expresses its gratification on

the increased percentage of members insured and expresses the hope that the percentage will materially increase each year We furthermore hope that each delegate will use his influence to

TABLE II

as large as I would have liked or as it should have been, was fairly good Sixteen per cent of the Albany County members were present, eight per cent. of Columbia County, twenty-seven per cent of Schoharie County, two from Rensselaer County, two from Ulster County, none from Sullivan County

There were nine from Albany County not listed in the Medical Directory for 1925, five from County Societies outside the district, together with Dr Haven Emerson, New York City, the President, Dr George M Fisher, the Secretary, Dr Daniel S Dougherty, the President elect, Dr J E Sadler, Dr O S Wightman, Editor of the Journal, Dr Frank Overton, Executive Editor of the Journal

The program, a varied one, was carried out in full both morning and afternoon A detailed account of the same was printed in the Journal, issue of October 1st, 1926

The Annual Clam Bake of the Albany County Society was given in the evening at McGowan's Grove It was largely attended and very enjoyable A program for the ladies present was arranged There were no dull hours during the entire day and evening

I could not give the time that should have given to the working of the various Societies

(seven in number) comprising the Branch I visited the Society meetings of four of the counties The majority are active and doing good work Some I am sorry to have to report as being in a quiescent state

Before closing my report, I would like to speak of the desirability of changing the geographical make-up of the District, if this be possible From Rensselaer County on the north to Sullivan County on the South is a long distance, not all good roads The member from northern Rensselaer or southern Sullivan should be elect to attend a meeting held in a remote portion of either County, would, from necessity, have to be away from his work two or three days

I desire to express my appreciation of and thanks for the attendance of the Officers of the State Society and to Dr Emerson as well, for the valuable papers presented To my fellow Officers I am truly grateful for the assistance given I bespeak for Dr Vander Veer, President-elect, the hearty cooperation of the entire membership of the Branch

Respectfully submitted,

CHARLES P MCCABE, *President*

---

## REPORT OF THE COUNCILLOR OF THE FOURTH DISTRICT BRANCH

*To the House of Delegates*  
Gentlemen

I herewith submit my annual report of the Fourth District Branch

This Branch, with the exception of the cities of Johnstown, Gloversville, Saratoga and Glens Falls and the Counties of Montgomery and Schenectady, might be said geographically to be within that territory known as the Adirondacks This vast region is so well known that it needs no description It differs from the rest of the State in many respects The months from June to October are the only ones on the average that are free from snow This makes getting about to see the sick a serious matter at times The permanent medical men resident in this region are a fine type of resourceful, capable doctors

Because of isolation and bad roads these men

have lacked contact with their fellow medical men and the consequent inspiration such contact brings

The momentum and attraction of mass movement should not be forgotten and so far as organized medical effort can go to correct this it should be done.

For example, during the vacation period from June to October organized medicine could well afford to send some of its best men to this region to give post-graduate instruction

The Annual Meeting held last autumn at Plattsburg was well attended and the physicians and citizens of Plattsburg proved themselves most generous hosts

Respectfully submitted,

HORACE M HICKS, *President*

March 15, 1927.

---

## REPORT OF THE COUNCILLOR OF THE FIFTH DISTRICT BRANCH

*To the House of Delegates*  
Gentlemen

A joint meeting of the officers of the counties of the Fifth District Branch was held last June at Syracuse Representatives from five

counties were present and in addition, Dr Joseph S Lawrence

At this meeting a program was outlined for the counties of the District This has been well carried out in some counties and pretty well in others

10th of November, 1926, and as far as I am able to find out, showed a larger attendance than any other meeting of the First District Branch in several years. It was intensely interesting by reason of the addresses by Dr George M Fisher, President of the State Society, Dr Daniel Dougherty, Secretary of the State Society, Dr Nathan B Van Etten, Dr John Prescott Grant, Dr William Sharpe, Dr Arnold Jackson of Madison, Wisconsin, and others of equal importance.

At this time I wish to extend to Dr Samuel J Kopetzky, Chairman of the Scientific Committee of the State Society, my personal thanks for the very excellent assistance he rendered in arranging the program for this meeting.

Previous to the annual meeting two conferences were held at the suggestions of the Executive Committee of the State Society. They consisted of the Presidents and Secretaries of the various component societies in this District, together with the Executive Officer, Dr Lawrence, and I am very confident that these conferences were productive of a great deal of good, for in my opinion they aroused an interest in the First District Branch which we

have not seen in a good many years. I certainly recommend that they be continued.

The one great trouble in the past has been that the District Branches have been more or less a one-man affair and the full force and spirit of the various District Branches have not been felt as they should have been. Closer contact between the Officers of the State Society and the various component county societies can be brought about through means such as these, and thereby increase the interest that up until a few years ago has been rather dormant.

It is impossible for the State Officers to visit all of the County Societies and it is through the means of the District Branches that they are brought in closer relation with the individual members. I believe that the past year or two has shown an awakening in the various branches that will result in a credit not only to the State Administration, but to the individual members.

Respectfully submitted,

JOHN A CARD, *President*

March 15, 1927

## REPORT OF THE COUNCILLOR OF THE SECOND DISTRICT BRANCH

*To the House of Delegates*

Gentlemen

The Annual Meeting of the Second District Branch was held January 7, 1927. An excellent report of that meeting has already been printed in the JOURNAL. Two of the papers read at that meeting have also been printed in the JOURNAL, viz Dr W H Ross' account of the activities of the Suffolk County Society and Dr E A Flemming's similar paper for the Queens County Medical Society.

The Nassau County Medical Society has continued its activities of previous years and is in a flourishing condition. One feature of the Nassau County Society's organization worthy

of note is the employment of a lay secretary, an arrangement that has proven very successful.

The Kings County Medical Society has continued all its activities of previous years, among which may be mentioned the Library, the program of Graduate Courses, the work of the Public Health Committee, in cooperation with other health agencies of the City, State and Nation, the Milk Commission, and the work of the Committee on Illegal Practice.

Respectfully submitted,

JOSEPH S THOMAS, *President*

March 15, 1927

## REPORT OF THE COUNCILLOR OF THE THIRD DISTRICT BRANCH

*To the House of Delegates*

Gentlemen

I beg to report the activities of the Third District Branch for the year 1926 as follows.

Soon after the Annual Meeting of the State Society a meeting of the Executive Committee was called at the Fort Orange Club, Albany, as the guests of the then First Vice President, now President-elect, Dr Edgar A Vander Veer. There was a good attendance and a tentative program was discussed, participated in

by all present, including Dr Joseph S Lawrence, Executive Officer, Dr H L K. Shaw, Chairman of the Legislative Committee and Dr MacFarlane, who were present by invitation.

In July another meeting was held in Hudson at the home of the Secretary, Dr C C Rossman, by invitation, at which time the program was practically completed.

The Branch Meeting was held at Albany on September 25th. The attendance though not

ties should be perpetuated as a sort of Executive Committee or Council of the Branch with perhaps a two-fold object. First, to help the Councillor to get a more or less accurate viewpoint of the conditions in the various County Societies in his District. In some of the Districts (the Sixth for example), it is utterly impossible for him to visit the County Societies, or all of them especially if he is a busy man and the distances are wide.

Second, to discuss the needs and problems of the various sections of the District and how to

meet them, and to assist in arranging a program for the annual meeting.

It would seem advantageous for the District Branch to discuss the many health problems and the subject of preventive medicine, and the relationship, attitude and degree of cooperation between the Medical Profession, the Medical Society, and the various lay health organizations operating in the District, with a view to better and closer relations and cooperation.

Respectfully submitted,

March 15, 1927 WILBER G FISH, *President*

## REPORT OF THE COUNCILLOR OF THE SEVENTH DISTRICT BRANCH

*To the House of Delegates*

Gentlemen

The work of the Seventh District Branch got under way at a meeting of its officers and the presidents of its various component County Societies held at Geneva last May, and presided over by Dr Joseph S Lawrence Executive Officer of the State Society.

Dr Lawrence explained the activities in which the State Society was engaged and outlined to us what problems could most properly be taken up by the District Branch and the County Societies. This meeting was most helpful in showing us how important some of the problems were, especially the toxin-antitoxin campaign, which was being fostered by the State Society. Dr Lawrence emphasized that this campaign against diphtheria was the biggest thing to be done by the Society this year.

At the time of the meeting five of the seven County Societies had endorsed this movement. During the year the other two County Societies gave it their endorsement, making our District 100% behind this movement.

Our annual meeting was held on September 29, 1926 at the Geneva Country Club. Nature kindly gave us an unusually fine day, sandwiched between several rainy ones before and after that date. The physicians evidently thought that if they worked all the rainy days they were entitled to take the one pleasant day off and join their fellows. The attendance was large, being equaled by the attendance of only one other District meeting in the State.

The program was marked by two splendid papers on subjects in which the State Society was specially interested. "Auburn's Experience with Toxin-Antitoxin" was read by Dr George C Sincerbeaux of Auburn. This paper and the

remarks by Dr Lawrence, Executive Officer, stimulated much discussion and inquiry about the subject. Dr B J Slater of Rochester gave the results of a survey of post-graduate work in the District. This report showed that the classes had been well attended and much interest shown in them. The papers on clinical subjects were, "The Early Diagnosis of Diabetes" by Dr Floyd R Wright of Clifton Springs, "The Importance of the Early Diagnosis of Urologic Pathology" by Dr Henry G Bugbee of New York City, and "Essential Hypertension" by Dr Clayton Greene of Buffalo. The latter two readers were guests of the District Branch.

The District Branch was honored by the presence of Dr George M Fisher, President of the State Society, Dr Daniel S Dougherty, Secretary of the State Society, and Dr Frank Overton, Executive Editor of the State JOURNAL.

The County Societies in the District are all live and active societies. The meetings are held regularly and are well attended. Cayuga County Society holds ten meetings yearly, while the other six societies hold four a year. A committee has been appointed in the Ontario County Society to consider the plan of holding ten meetings a year.

The Monroe County Society held a series of clinics for their members in the early part of the winter. The latter society is carrying on a most active and energetic campaign to eradicate diphtheria from their communities.

It is a pleasure to report the high standards maintained by all the County Societies in the Seventh District, and the very high average attendance at the meetings.

Respectfully submitted,

CLAUDE C LYTLE, *President*  
March 15, 1927

## HERKIMER COUNTY

They have carried out post-graduate teaching in obstetrics and plan to extend it along other lines. Their scientific program consists of papers by local men, supplemented by papers by men outside of the county.

## JEFFERSON COUNTY

This County is most active and progressive. They have carried out an extensive program and have had well organized and well attended post-graduate courses held alternatively in Ogdensburg and Watertown. Their scientific program consists of one given once a month by local men and the next by an outside speaker. The interest is keen.

## MADISON COUNTY

This County has no large urban population, but men get together three times a year, during the spring and fall for a scientific meeting and then a social affair in the summer. This County has approved of the health propaganda advocated by the Society and has attempted to carry out examination of pre-school children and the diphtheria immunization as far as they are able.

## ONEIDA COUNTY

This Society has kept closely in touch with Public Health propaganda. They are actively carrying on the annual diphtheritic campaign and the periodic examination of children. A site has been purchased for a county sanatorium. Post graduate study has been resumed. The members of the Society seem eager for this

type of work. The scientific meetings have been held regularly and are most harmonious and enthusiastic.

## ONONDAGA COUNTY

This County has adopted the policy of having some outside man of another community to address each meeting. It has also been the policy for this Society to combine some social event with each meeting. Two meetings a year are held at the country clubs where golf is enjoyed. The other two meetings are held at the hotel preceded by dinner. The attendance varies between 200 and 300. The Legislative Committee has done a great deal in its effort to aid medical legislation. The Committee on Public Health is putting over a plan of yearly health examinations. They have also taken an active part in the State Society plan for diphtheria prevention. The Milk Committee continues to check up on the certified milk supply of the community.

## OSWEGO COUNTY

Oswego County is active and sends representatives of the County meetings of the adjacent counties.

## LEWIS COUNTY

This County has difficulties in conducting regular meetings due largely to the small number of men practicing in this County as well as to the difficulty and distances of travel.

Respectfully submitted,

CHARLES D. POST, *President*

March 15, 1927

## REPORT OF THE COUNCILLOR OF THE SIXTH DISTRICT BRANCH

To the House of Delegates

Gentlemen:

The Sixth District Branch covers a comparatively large territory of the State and embraces approximately 8,300 square miles of territory. It is about 150 miles from its eastern to its western limit and its northern and southern boundaries are from 45 to 73 miles apart. In this territory there are 10 counties and no large cities, Binghamton being the largest.

According to the last edition of the Medical Directory of the State Society there are 620 physicians in the District of which 454 are members of their County Medical societies, a little over 73½%. This of course is not absolutely accurate as some inaccuracies are bound to occur in such compilations and changes are constantly taking place.

The percentages of memberships in the several counties run as follows: Broome 85, Schuyler 84, Tompkins 83, Chenango 76, Steuben 70, Tioga

67, Delaware 67, Cortland 66½, Chemung 65½, Otsego 63½.

A new alignment of territory between the eight districts which is to come before you at the May meeting, would, if passed as proposed, take Schuyler and Steuben from the Sixth District. Both counties object to this change and prefer to remain in the Sixth District.

A meeting of the officers of the Branch and the Presidents of its County Societies was held several months previous to the Branch meeting for the purpose of discussing the conditions in the District and outlining a program for the annual meeting. The result was a program of much wider interest than usual and a much better attendance. The program took up the public health activities of several County Societies. For a detailed account I refer you to pages 835 and 836 of the October number of the State Journal.

I believe such conferences of the officers of the Branch and Presidents of its County Socie-

For list of officers of County Medical Societies, see the JOURNAL April 15 issue, page xxx

### THE ANNUAL REPORTS

The Annual Reports of the Officers and Committees of the Medical Society of the State of New York appear on pages 451-490 of this JOURNAL. The publication of the reports in advance of the annual meeting is an innovation that was authorized by the last House of Delegates, and for it the Society has the precedent of the American Medical Association, the Michigan State Society and the societies of some other states.

The object of the advance publication of the reports is to inform all the members of the State Society regarding its activities. While reprints are mailed to every delegate before the annual meeting, yet it is hoped that every member will read the reports carefully, for they will give him a comprehension of the wide range of activities carried on, and the scope of the numerous contacts which the society makes with physicians and the public.

## REPORT OF THE COUNCILLOR OF THE EIGHTH DISTRICT BRANCH

*To the House of Delegates*

Gentlemen

The past year has been noteworthy for the activities of the County Medical Societies in the district. The anti-diphtheria campaign was endorsed by all of the counties and active work was carried on especially in Erie, Niagara and Cattaraugus Counties. Erie County has adopted a slogan, "No Diphtheria in Erie County in 1930."

The work done under the Millbank Fund in Cattaraugus County, has continued during the year. It is to be regretted that friction developed between the County Medical Society and the public health workers. This does not mean that the organized medical profession has been opposed to the demonstrations of public health measures, but rather that certain individuals have shown unfortunate lack of tact and that misunderstandings have occurred through a failure of both parties to the controversy to get together. The County Medical Society late in the year adopted a resolution declaring its willingness to cooperate in the movement. It was largely as a result of this situation that the Public Relations Committee, mentioned later in this report, was organized.

In Chautauqua County the County Committee on Tuberculosis and Public Health has been very active and public health committees have been organized in every community. This Committee plans to actively enlist the medical profession and to have it represented on the Committee in each community. The physicians of the county are entirely sympathetic with the work being done by this lay organization and it is believed that the campaign will be actively supported by the County Medical Society.

Post graduate courses have been given in Erie, Niagara, Genesee, Chautauqua and Cattaraugus Counties. It is likely that this work will be extended during the coming year. Erie County has set an example for all of the other counties in the District. In addition to the anti-diphtheria campaign, already mentioned, the Erie County Society has published a bulletin which has been widely distributed to the physicians not only of Erie County but of the other counties in the District. At a testimonial dinner to physicians who had practiced fifty years or more a genuine spirit of good will and professional enthusiasm was aroused. An attractive booklet listing the operations for clinical study in and near Buffalo was published and distributed by the Erie County Medical Society.

The Annual Meeting of the District Branch was held at the Buffalo City Hospital, and as usual was rather poorly attended. The President and Executive Officer of the State Society travelled the length of the State in order to address

a mere handful of physicians at the morning session. On account of the chronic lack of interest in these Annual Meetings I believe that the most effective work of the District Branch Society will be done by round table conferences of the Executive Committee. Three of these meetings were held in Buffalo during the year, on June 3rd, August 6th and March 4th. These were evening meetings and it was found that the officers of the Society had so many topics for discussion that even an entire evening did not allow sufficient time.

At the meeting of the Executive Committee on March 4th, six of the eight Counties of the District were represented. In addition to the members of the Committee the following gentlemen were present and took an active part in the discussion: Dr Archibald Dean, District Health Supervisor, Dr Joseph Lawrence, Executive Officer of the State Society, Dr George Critchlow, Chairman of the Legislative Committee of the Erie County Society, Dr Francis Fronczak, Health Officer of Buffalo, and Dr Hourigan of Buffalo.

The function of the Public Relations Committee of the State Society was explained and the Committee decided that each County Society should have a similar committee instructed to get in touch with the various public health agencies in the County, in order that the organized profession should be able to take a more intelligent and active part in public health work. The resolutions endorsing County Health Units, which were adopted by the Joint Committee on Public Relations of the State Medical Society and of the State Charities Aid Association were carefully considered and after full discussion the Committee approved of these resolutions. It was moved and carried that the Secretary send a copy of the resolutions to each County Medical Society in the District with the recommendation that if the plan be approved the County Societies petition the Board of Supervisors to organize a County Health Unit.

Dr Hourigan gave a talk on the Miller Bill, and urged the Committee to do everything possible to stimulate in the County Societies greater interest in the problems of workmen's compensation. The meeting adjourned at 11 o'clock to permit some of the members to catch their trains, but so great was the interest that several of the physicians continued the discussion informally after adjournment.

Our experience with these Executive Committee Meetings, convinces me that they should be given a more prominent place in the work of each District Branch Society.

GEORGE W. COTTIS, *President*

March 15, 1927

side which paid the fee. In this case, the alienists insisted on being free to judge the mental condition of the man in the light of

their consciences and their scientific knowledge, regardless whether their findings embarrassed or aided their own side"

---

## LECTURES ON THE COUNTY MEDICAL SOCIETY

After a medical student graduates, the county medical society takes the place of his medical school. The close social contacts which he has formed during four years of study will be reformed from among the members of the county society. The leaders of the society will take the place of his professors. The honors, activities and opportunities of the university will again be offered to him in the normal program of work of the society. The organization will offer opportunities for research, for writing, for lecturing, and teaching. It will also invite the public spirited graduate to discharge his civic duty at the time when medical work

of any kind is eagerly sought by the young man just starting in practice. The younger doctor's career, planted and nurtured in the medical school, will reach its fruitful maturity in the county medical society under the influence of his older colleagues.

It would seem self-evident that medical students should be instructed regarding organized medicine and their duty and privilege to take an active part in the medical societies of the communities in which they practice. The Long Island College Medical School includes such instruction in a course of intimate talks on the civic duties of physicians.

---

## LOOKING BACKWARD

### THIS JOURNAL TWENTY-FIVE YEARS AGO

New York State Laboratory —This Journal for May, 1902, contained the following item of news, coupled with a hope that has remained unfulfilled:

"The Antitoxin Laboratory of the State Department of Health, which was inaugurated in 1901, is located in the Bender Laboratory, Albany, while the animal house is located several blocks away with a capacity of fifteen large animals. The State has already made an appropriation of \$20,000. The object of the laboratory is to manufacture under State control the various antitoxins for use in all State institutions and for the indigent poor. Diphtheria and tetanus antitoxins are now ready for use. It is hoped that effective antitoxin for tuberculosis, typhoid fever and various other infectious diseases may be obtained by original research. The laboratory is under the direction of Dr. Herbert D. Pease."

The same issue contains an article on the use of paraffin in surgery, especially in deformities of the face—an operation of which little is

now heard. The article closes with the following observations:—

"Restoring sunken cheeks by paraffin injections should take the place of the mechanical device now used by dentists for that purpose and known as 'plumpers'. This contrivance consists of a thickening of the upper plate at the sides, to a degree that when the plate is worn the cheeks are made to bulge outward. It does not restore natural expression and is cumbersome and difficult for the patient to manipulate while speaking or eating. Paraffin will give much better satisfaction."

"The injection of paraffin is not entirely free from danger, and it is stated that abscesses have occurred, also sloughing. In one case symptoms of tetanus were observed after an injection, and another case developed evidence of pulmonary embolism. So far I have seen no unfavorable symptoms. In all the cases in which injections were given, varying from one drop to half a dram at an injection, there was no reaction and no change in the tissues."

## OUR ADVERTISERS

A periodical which is the organ of a State Medical Society must have at least three departments—scientific, organized activities and advertisements

The advertisements are much more than the means of money making, they are educative. In regard to new books their review is educative to such a degree that most medical journals conduct that department as unbiased comments on their value, which the prospective buyers accept as authoritative.

There is a prejudice on the part of some physicians against advertisements of articles which have but small therapeutic value. But doctors will be compelled to use such products so long as human nature demands something to take or use. There still exists an *art* of prescribing although its *science* in respect to many preparations may have almost vanished.

The value of a medical journal to advertisers is in direct proportion to the number of its readers, and that may be far greater or less than the circulation figures. A children's picture paper will be read by everybody in the doctor's family,—the medical journal will be read by only one.

Doctors are interested in the advertising section of a medical journal quite as much as in its scientific and news departments. The

April first issue of this Journal indexed its advertisers under seventeen headings, from abdominal supporters to waters, and every advertisement was of direct interest to the average doctor. While he might not buy some of the articles advertised, he probably has patients who would do so. Only now and then, for example, would a doctor need an invalid elevator, but he probably has several patients who would be interested in them if they knew where they could see one. Then, too, how many doctors know what an invalid elevator can be installed in a home at a reasonable price?

The advertising index of this Journal contains about the same number of references as the general index,—52 and 48 respectively in the April first issue. Note how much general information one may get from the advertisements. For example, What is the importance of food in the diet of the artificially fed infant? The answer is found in an advertising page of the April first Journal.

Read the advertising pages of this Medical Journal. The more you know about the products that are advertised, the more likely will you be to buy or recommend those articles, and the greater popularity will the Journal have among the advertisers.

## EXPERT MEDICAL TESTIMONY

The doctor seeks the truth and so also does the Judge on the bench and the two opposing lawyers. But what is truth? The actors in a law court drama are the two lawyers, each bound to uphold the interests of his own client. When medical testimony is necessary, each litigant hires a physician for the express purpose of testifying regarding points favorable to his side of the case, and possibly the court appoints a third doctor to give his opinion regarding both sides. Then at the trial, each physician tells his story, usually extempore, and in an unusual and partly hostile environment. The three stories are bound to be somewhat conflicting in minor details, which the cross-examining lawyer magnifies in an attempt to discredit the witness. The system is not conducive to the development of truth, and on the other hand it magnifies the apparent disagreements among doctors until the jury-men and the public generally have come to consider that an expert physician on the witness stand is on the same plane as the ignorant laborer whose judgment, such as it is, is swayed by prejudice.

If doctors had their own way, they would settle their differences and reconcile their con-

flicting opinions in private before they go on the witness stand. To get the doctors to do this may seem like a Utopian dream, however the difficulty lies not with the doctors so much as with the lawyers. The physicians would be able to agree on their testimony, provided the opposing lawyers would agree to permit them to do so.

The lawyers engaged in a murder trial in Queens County set a most excellent example, in that those for the defense chose two psychiatrists, and the District Attorney two more for the purpose of determining the sanity of the accused man. The four doctors examined the patient together, and rendered a unanimous opinion that he was sane. This opinion was accepted by the lawyers and the Court and the trial proceeded without the question of insanity being raised.

The *New York Times* says

"The procedure under which the defendant's plea was destroyed by his own alienists is a revolutionary novelty in criminal law. The profession of psychiatry for many years has rested under the reproach that a psychiatrist would testify that a man was sane or that a man was insane, according to the desire of the

**The Course of Acute Rheumatic Arthritis after Treatment of Inflammatory Processes in the Upper Air Passages**—Osten Holsti (*Acta Medica Scandinavica*, January 26, 1927, lxx, III-IV) emphasizes the fact that, while treatment with the salicylates is usually effective in controlling an acute attack of rheumatism, relapses seem to occur as frequently as before the introduction of this drug. He has followed 35 cases of acute and relapsing rheumatic arthritis for four and a half years. In cases in which there was a history of dyspeptic troubles, suggesting infection through the gastroenteric tract, a special diet was ordered, in others, careful protein therapy was tried, and in still others, where the inflammatory process in the upper air passages was very marked, the treatment of the latter was begun before the patient became afebrile. No harmful effect was seen from starting this treatment so early. As a rule, however, no surgical treatment was undertaken until the patient had completely recovered from the acute rheumatic attack. No relapse occurred in any purely rheumatic case in a patient who had reached puberty. Relapses occurred in three cases, two of which were complicated by other diseases (hemophilia, gonorrhea), and in only one case of purely rheumatic infection. This was in a child of 10 years. The relapse was preceded by a head cold and sore throat and terminated fatally. The experience in this series of cases affords some evidence that the treatment of inflammatory processes in the upper air passages is a measure which is directed toward healing of the most important focus for the development of the relapses. Signs of general poor health were a frequent finding before as well as after the treatment. The course of the purely rheumatic disease in adults was, however, much more benign after the institution of treatment of the upper air passages than prior to this.

**How Latent Foci of Tubercle Become Activated**—A. Arnstein, who is at the head of a tuberculosis sanatorium, attempts to answer this question. Among the general conditions which are reputed to possess this power of activating tuberculous foci are the acute exanthemata of childhood, whooping cough, influenza, gestation, and any others which tend to reduce the resistance to disease. The author has repeatedly seen individuals in their seventies and eighties suffer a reawakening of a tuberculosis which had become latent at the time of puberty, the foci being apical. In such cases the possibility of a reinfection from without is suggested, but all of the evidence is against such a supposition. We may, of course, in such cases speak of reinfection, but it is always endogenous. The author advances the

theory that arteriosclerosis favors the lighting up of an old tuberculosis, and explains this by the assumption that arteriosclerosis notably reduces the general vigor. On the other hand, he admits that the two conditions, arteriosclerosis and reawakening of tuberculosis, may have a common origin, such as worry, excitement, overexertion, or alcoholism. Incidentally, the author explains why cancer and tubercle sometimes coexist, although in theory this should not be the case. The cancerous cachexia, which so greatly lowers vitality and resistance, certainly makes it possible for old tuberculous foci to be activated. In the present study, the author is interested exclusively in the reanimation of insignificant early tuberculous foci. He has notes of 176 patients in this group. Of the conditions which appeared to pave the way for a reawakening of the long latent apical infection, the frequency may be arranged as follows: Arteriosclerosis, 52, malignant tumor, 42, disease of the heart and aorta, 24, emphysema of the lungs, 15, acute infectious diseases, 16, and scattering, 27. It will be manifest that the author is dealing almost entirely with the reawakening of the disease in subjects over 50 years of age.—*Klinsche Wochenschrift*, February 12, 1927.

**Local Treatment of Erysipelas with Besredka's Streptococcic Filtrates**—K. T. Gloukhoff of the Institute of Experimental Medicine of Leningrad states that after the streptococcus of erysipelas has penetrated into the skin or mucous membrane it is propagated along the lymphatics, but if the quantity is in a certain excess there is rupture into the subcutaneous (or submucous) tissue with formation of local phlegmons and development of general sepsis. In the preparation of the filtrates the author began with an individual strain of the coccus but gradually increased the number to nine. These he cultivated for twelve days at a constant temperature of 37° C. and then passed the cultures through a Chamberland filter. The filtrates thus obtained were sown anew and so on. The final filtrates were used as dressings, as such, or mixed with lanoline and vaseline, all dressings being changed every 24 hours. The course of untreated erysipelas is notably capricious, patients often recovering spontaneously, which makes it difficult to appreciate the influence of treatment. The author obtained some control, however, by applying a dressing to certain regions only—in bilateral facial erysipelas to one-half of the face. With this check it was often possible to note remarkable response to the treatment, the treated half of the face would become normal in a short time while the untreated half showed no change. The response was not always so prompt, but in general good results were obtained after one, two, or three dressings. In some cases the filtrate was

# MEDICAL PROGRESS

**Treatment of Influenza.**—Julius H. Hurst, writing in *The Lancet*, February 19, 1927, ccxii, 5399, recommends in the treatment of influenza a formula which did exceedingly good service in the epidemic of 1918. The remedy consists of a capsule containing quinine hydrochloride, camphor monobromate, hexamethylenamine, of each two grains, and methylene blue one grain. These drugs are well mixed and pounded up together and the capsule filled in this proportion. Smaller doses are used for children. One capsule is given at the onset of the illness, followed if necessary, in four hours by a second. Not more than four should be used in twenty-four hours, usually three capsules are all that are required, two in the first twenty-four hours and one in the second. In addition, rest in bed, elimination—laxatives—plenty of hot tea, freshly made with cream and sugar added, are indicated. No coal-tar derivatives, salicylic acid products, or other heart depressants should be given.

Professor Trumpp of the Munich University faculty, who claims never to have lost a patient with grippe during all the years of his activity, feels it his duty to impart his method of treatment to the profession at large, while still realizing that consistent good luck may have been the vital element (*Muenchener medizinische Wochenschrift*, February 4, 1927). He does not darken the sick room, although he protects the patient's eyes from unpleasant contacts, and he sees that the patient gets an abundance of outdoor air, which is the best remedy for the tormenting headache. Fresh and cool air is in fact a polyvalent remedy. At the same time he makes the patient comfortable and does not expose him to any draughts. He is very particular about the mattress, pillows, etc., all of which must be of firm texture and of a non-heating type. If the patient is most comfortable when propped up this should be done with books or wooden blocks rather than by endless cushions and pillows. The patient's comfort is the last appeal as well as the first consideration. In regard to drug treatment there is certainly a poisonous principle which must be expelled from the body, and, further, drugs which we frequently give merely to meet symptomatic indications are recommended by the author as etiological remedies, he gives a mixture of benzoic acid, camphor and amidopyrine, very largely because it attacks the disease in the citadel. The author avoids all essential cold applications and finds that a very

brief warm bath is grateful. He agrees with the custom of some American practitioners in giving adults a hot grog or toddy at the outbreak of the case, this especially at the close of the warm bath, to prevent chilling, which may be the more indicated because he cools the patient after his bath with a douche. The author evidently relies more on expert nursing than he does on medical, or medicinal treatment.

**The Calcium Content of the Blood in Tuberculous Children.**—The favorable results following the administration of calcium lactate, and at times the intravenous injection of calcium chloride, in children suffering from tuberculosis with hemorrhage, led Harry R. Litchfield (*Archives of Pediatrics*, February, 1927, xlv, 2) to investigate the problem of calcium in the blood. The study was carried out in the children's division of the Brooklyn Home for Consumptives. The calcium in the blood was determined by the de Waard technique in five cases of primary, four cases of secondary, and three cases of tertiary tuberculosis, before treatment and eight weeks and five months after treatment. Supplementary to the usual hygiene management, these patients were given 5 grains of anhydrous calcium chloride, 1 grain of iron, and 60 minims of cod-liver oil after each meal. In addition, one tablet of parathyroid extract was given three times a day, because of the emphasis placed on the close relationship of calcium metabolism to the parathyroids. The author concludes that there is a definite calcium deficiency in the blood of tuberculous patients. The far advanced cases showed the lowest calcium content in the blood. But, while calcium is of great service in the healing of tuberculosis, it does not have any decided therapeutic value in advanced tuberculous patients, as evidenced by the fact that all the author's cases of the tertiary type terminated fatally, although there was a slight increase in the calcium content after a few months' treatment. There was a remarkable increase in the calcium content of the blood after five months of treatment in the primary and secondary cases, in some of which it reached almost the normal limit. This indicates that calcium is an important factor and should be employed as a specific, for, when the calcium content of the blood is increased to normal, the patient is helped to combat the disease.

entiate cases of this type from the usual run of hypertonics in which the prognosis is unfavorable in this respect. There is no evidence in this group of serious organic cardiac, renal, or cerebral disease and we must regard them as functional in nature, despite the evidence of arteriosclerotic change. During the long observation periods ranging from 6 months to 2 and 2½ years, all of the known hypotensive remedies were tried out but the author attributes no benefit to any of the drugs or physical remedies with the exception of repose. The first patient suffered coincidentally from peroneal paresis and was forced to lie abed, and the other two were below the standard of normal health and activity, one suffering from bronchitis of long standing with dyspnea while the other was in the initial stage of amyotrophic lateral sclerosis, and both were in a state of poor nutrition. These two patients were both of the asthenic habitus. In regard to visceral disease there was no doubt as to the integrity of the kidneys, but all of the women showed some enlargement of the left ventricle and the two asthenics showed in addition organic disease of the aorta (elongation and dilatation respectively), although there was no impairment of cardiac function, and no symptoms of any sort. The chief value of these cases in the author's opinion is that they illustrate the great importance of absolute rest in hypertension — *Klinische Wochenschrift*, February 5, 1927

**Transmission of a Drug Idiosyncrasy**—M Lang and O Der relate the case of a psoriatic male patient with dementia precox who after a small dose of quinine developed a generalized rash, accompanied by a temperature of 104° F. He developed the same picture every time he took five grains of the drug whether by the mouth or intracutaneously. The local application produced no reaction. One cc of the patient's serum injected into a guinea pig and followed by quinine injection produced death in convulsions. The same fluid was next tested on rabbits, using the patient's normal serum as a control. The serum taken during the course of the quinine idiosyncrasy, when injected intravenously killed a rabbit on the eighth day. Both the animals mentioned showed on autopsy multiple internal hemorrhages. Finally a bit of skin from the patient was implanted beneath the skin of the abdomen of a rabbit, and the animal received an injection of quinine, and while some of the injection points gave negative results others gave respectively a

hyperemic reaction and ulceration. This form of transmission is known technically as the passive, and has previously been obtained with iodoform, iodine, and arsphenamine. The death of the guinea pig was preceded by anaphylactic phenomena and the author believes that it is impossible to draw a line between true idiosyncrasy and anaphylaxis. In one rabbit experiment an injection of quinine preceded the injection of serum but the result was the same as when this order was reversed. The authors are at work on a monographic account of the entire subject of drug idiosyncrasy — *Muenchener medizinische Wochenschrift*, January 14, 1927

**Vaccination and Angina**—G Koch writing in the *Deutsche medizinische Wochenschrift*, January 21, 1927, on vaccination against smallpox, says that in certain very rare cases we see a marked inflammatory reaction with swelling of the regional lymph nodes, an erythematopapular eruption or generalized vaccinia. Quite recently a new form of rare vaccine injury has been described under the designations of serous meningitis and encephalitis, the nature of which is as yet obscure. In 1922 Orgler called attention to redness and swelling of the tonsils on the fifth to sixth day after vaccination, in a small proportion of which cases there was a typical follicular angina. The author made the same observation at about the same time as regarded redness and swelling of the tonsils, but for some time has seen no typical angina. The earliest period was the sixth day following vaccination and the duration was two or three days. Finally he saw a case of follicular angina with a temperature of 104° F. Orgler assumed that in such cases the tonsils were already infected and the vaccination served to activate the microorganisms. No other post-vaccinal development is mentioned except hematuria which has been known to supervene in predisposed children. While harm from vaccination is very slight, means should be taken to reduce the risk. Intracutaneous vaccination presents no advantage over the scratch method but rather the reverse. In the author's sole case of follicular angina it is of interest to note that the two previous attempts to immunize the child had given negative results, so that the author made an unusual effort to have the vaccination take. It is a remarkable fact that the younger the infant the less chance of vaccination harm, as nurslings show more resistance than older children. "Vaccinate early with but one scarification" is the author's advice.

also injected into the subcutaneous tissues. Thus far 129 patients have been treated with the filtrate, but 50 of these were very mild, leaving 79 which were medium or severe. The number of severe cases treated was 26 and there was no mortality. A corresponding series treated before the introduction of the filtrates presented six of the severe type and two of the patients succumbed—*Annales des l'Institut Pasteur*, February, 1927.

**The Treatment of Infantile Paralysis**—Harry Eaton Stewart describes the benefits to be derived from physiotherapy in the treatment of infantile paralysis, which have been largely overlooked by the profession in general. A method of treatment, first employed by Dr. William Benham Snow, in the acute stage of the disease consists in the application of the Morton wave from the static machine to minimize pressure destruction in the cord. A flexible metal ribbon electrode is applied along the spine in the affected region, with a spark-gap of ten to twelve inches, in order to obtain sufficient voltage. Two other procedures of value during the active stage are the use of radiant light and the waterbath at 95° to 102° F. For many reasons radiant light and heat are to be preferred. The Morton wave may be applied with the hope of obtaining beneficial results in any case of not more than six months standing. In chronic cases adequate treatment must aid nutrition, stimulate the muscles, and re-educate nervous control. The nutrition of paralyzed and atrophic muscles may be stimulated by external heat, radiant light, the paraffin bath, whirlpool bath, superheated dry air, or diathermy. The sinusoidal wave, and galvanic and faradic currents are then helpful in minimizing the muscular atony and atrophy following nerve injury, they should be applied in sufficient dosage to produce a very few gentle contractions in partially regenerated nerves. Assistive active and passive exercises aid in keeping in function the mental and motor pathways which tend to deterioration from disuse. There seems to be no reasonable span of years which precludes the possibility of improvement. In the army there were cases of eight and ten years standing which showed improvement under this plan of treatment. Continuous treatment for at least three years is justifiable unless all progress has definitely stopped for a period of months. The closest cooperation with the orthopedist is essential to the end that proper braces and operative procedures may be instituted when needed.

In discussing this paper, Dr. William Benham Snow related his first experience with the use of the Morton wave in the treatment of infantile paralysis in the case of a boy seen two weeks after the onset of the disease. Under this treatment the boy, whose lower extremities were

paralyzed, was able to walk at the end of two weeks and made a satisfactory recovery. The speaker had seen many similar cases. There was no stage of poliomyelitis in which more remarkable results were seen than in acute cases treated by the methods described. The reports of the Rockefeller Institute stated that the germs of poliomyelitis were very susceptible to light. Therefore the application of light over the spine should arrest the progress of germ development, and together with the use of the static current would probably contribute more to the relief of the condition than other methods. Dr. Stewart was entirely right, he said, as to the management of the chronic cases—*Physical Therapeutics*, March, 1927, xlv, 3.

**Diabetic and Hypoglycemic Coma**—It is perhaps not generally known that two quite different forms of diabetic coma are now recognized. One is the ordinary coma of diabetic acidosis while the other, only recently recognized, is the result of excessive reduction of blood sugar such as may result from large doses of insulin. E. Wiechmann, writing in the *Muenchener medizinische Wochenschrift* for January 8, 1927, takes up the subject of the differential diagnosis of these forms of coma. It is possible for the patient to pass from ordinary diabetic coma into the hypoglycemic form as a result of insulin. In the diabetic form the respiration is affected, while in the other form it is normal, in the former, the pulse is small and frequent but regular, while in the hypoglycemic form it is rapid and markedly arrhythmic. These two differential points make up most of our knowledge, which therefore stimulates us to the recognition of new ones, and the author thinks he has discovered one in the temperature which he has found thus far invariably subnormal and at times at the collapse level. By contrast he has found such temperatures in the diabetic form in rare cases only. According to all clinicians since Frerichs the temperature in diabetic coma is very variable and may be either subnormal or febrile. At present the numerical chance is greatly in favor of the hypoglycemic form if a patient enters the hospital with coma, for while these low figures are the rule in the diabetic they occur but rarely in the hypoglycemic form. It is of course well known—or should be—that urinary examination is not dependable, for in undoubted diabetic coma there may be no trace of acetone bodies in the urine.

**Pathogenesis and Prognosis of Essential Hypertonus**—N. Tolubejewa relates three cases of arteriosclerosis and hypertonus in elderly women in whom after prolonged treatment the blood pressure was slowly brought down approximately to normal. He asks what differ-

entiate cases of this type from the usual run of hypertonics in which the prognosis is unfavorable in this respect. There is no evidence in this group of serious organic cardiac, renal, or cerebral disease and we must regard them as functional in nature, despite the evidence of arteriosclerotic change. During the long observation periods ranging from 6 months to 2 and 2½ years, all of the known hypotensive remedies were tried out but the author attributes no benefit to any of the drugs or physical remedies with the exception of repose. The first patient suffered coincidentally from peroneal paresis and was forced to lie abed, and the other two were below the standard of normal health and activity, one suffering from bronchitis of long standing with dyspnea while the other was in the initial stage of amyotrophic lateral sclerosis, and both were in a state of poor nutrition. These two patients were both of the asthenic habitus. In regard to visceral disease there was no doubt as to the integrity of the kidneys, but all of the women showed some enlargement of the left ventricle and the two asthenics showed in addition organic disease of the aorta (elongation and dilatation respectively), although there was no impairment of cardiac function, and no symptoms of any sort. The chief value of these cases in the author's opinion is that they illustrate the great importance of absolute rest in hypertension — *Klinische Wochenschrift*, February 5, 1927

**Transmission of a Drug Idiosyncrasy**—M Lang and O Der relate the case of a psoriatic male patient with dementia precox who after a small dose of quinine developed a generalized rash, accompanied by a temperature of 104° F. He developed the same picture every time he took five grains of the drug whether by the mouth or intracutaneously. The local application produced no reaction. One cc. of the patient's serum injected into a guinea pig and followed by quinine injection produced death in convulsions. The same fluid was next tested on rabbits, using the patient's normal serum as a control. The serum taken during the course of the quinine idiosyncrasy, when injected intravenously killed a rabbit on the eighth day. Both the animals mentioned showed on autopsy multiple internal hemorrhages. Finally a bit of skin from the patient was implanted beneath the skin of the abdomen of a rabbit, and the animal received an injection of quinine, and while some of the injection points gave negative results others gave respectively a

hyperemic reaction and ulceration. This form of transmission is known technically as the passive, and has previously been obtained with iodoform, iodine, and arsphenamine. The death of the guinea pig was preceded by anaphylactic phenomena and the author believes that it is impossible to draw a line between true idiosyncrasy and anaphylaxis. In one rabbit experiment an injection of quinine preceded the injection of serum but the result was the same as when this order was reversed. The authors are at work on a monographic account of the entire subject of drug idiosyncrasy — *Muenchener medizinischer Wochenschrift*, January 14, 1927

**Vaccination and Angina**—G Koch writing in the *Deutsche medizinische Wochenschrift*, January 21, 1927, on vaccination against smallpox, says that in certain very rare cases we see a marked inflammatory reaction with swelling of the regional lymph nodes, an erythematopapular eruption or generalized vaccinia. Quite recently a new form of rare vaccine injury has been described under the designations of serous meningitis and encephalitis, the nature of which is as yet obscure. In 1922 Orgler called attention to redness and swelling of the tonsils on the fifth to sixth day after vaccination, in a small proportion of which cases there was a typical follicular angina. The author made the same observation at about the same time as regarded redness and swelling of the tonsils, but for some time has seen no typical angina. The earliest period was the sixth day following vaccination and the duration was two or three days. Finally he saw a case of follicular angina with a temperature of 104° F. Orgler assumed that in such cases the tonsils were already infected and the vaccination served to activate the microorganisms. No other post-vaccinal development is mentioned except hematuria which has been known to supervene in predisposed children. While harm from vaccination is very slight, means should be taken to reduce the risk. Intracutaneous vaccination presents no advantage over the scratch method but rather the reverse. In the author's sole case of follicular angina it is of interest to note that the two previous attempts to immunize the child had given negative results, so that the author made an unusual effort to have the vaccination take. It is a remarkable fact that the younger the infant the less chance of vaccination harm, as nurslings show more resistance than older children. "Vaccinate early with but one scarification" is the author's advice.

# LEGAL

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York.

## AN ERRONEOUS DECISION

On April second of this year, in the City Magistrate's Court sitting in the Borough of Richmond, Magistrate Bridges rendered a decision in the prosecution against a chiropractor which, in the judgment of the writer, was erroneous and unfortunate.

Acting under the instructions of the Attorney General, on January 24, 1927, Helena C. Brady, a policewoman, called at the office of Christian P. Eifertsen at 56 Bay Street, St. George, Staten Island. She was accompanied by a fellow policewoman, Frances Symon. On the bulletin board in the corridor of the building they found "Room 25, C. P. Eifertsen, Ph. C." They went to this office, on the door of which there was the sign "Chiropractor." Miss Brady was met in the outside office by a young lady who asked for her name and address and when requested to be allowed to see "Dr. Eifertsen" replied that he was busy at the time. Miss Brady waited for twenty-five minutes and was then shown into a small booth in the rear of the office and was asked to disrobe to the waist. She was given a white smock and told to have it open at the back. "The doctor wants to examine your spine," the young lady said. She then left the room, returning in a few minutes to the place where Miss Brady was sitting and said "The doctor will see you now." The two women then entered a small office and Miss Brady said "Are you Dr. Eifertsen?" and he answered "Yes." The defendant asked both of the women to be seated and Miss Brady then told him she was suffering from pains in the left shoulder and left arm between the shoulder and the elbow, that these pains had been of some duration, that she had been suffering from them for about three months, that she also had suffered pains in the back and front part of her head. "Doctor, do you think these pains will respond to chiropractic treatment?" she asked and the defendant answered "Yes, and chiropractic treatment is just the thing you need to remove the cause of these pains." She continued "Doctor, do you think chiropractic treatment will relieve these conditions?" to which he replied "I know that I can cure you and if I don't I shall remove my sign, I have cured many and I do not feel that I will have to remove my sign just for one person." Thereupon the chiropractor pressed heavily upon the base of Miss Brady's right ear and said

"There is nerve pressure there and that is the cause of your headaches in the fore part of your head." He then manipulated along her vertebræ toward the middle of the back and then toward the left shoulder. At the left shoulder he pressed heavily and when his patient indicated pain he said "This is the cause of your pain in the left shoulder and arm." He then referred to a chart on the wall where there were pictures of the human nerve system and pointing to a certain section of the chart declared "This is where you have that pressure." He then turned to where his patient was sitting on a stool and gave her head a sharp jerk first to one side and then to the other, causing a snapping sound. Then followed a series of manipulations in various positions, horizontal and vertical. He manipulated the vertebræ and gave it certain downward thrusts, giving the patient's head a sharp turn one way and then the other. The defendant then took what looked like a skeleton of the human spine and showed his patient how the bones press together and how they were pressing on a nerve, declaring that that was the cause of the pains in the shoulder and the arm.

When the defendant was asked what his fee would be he directed Miss Brady to see the young lady in the outer office, who, when interviewed, inquired if the "doctor" had said how many treatments would be necessary. Miss Brady answered that he had not but that he said to come the following day, and thereupon the young lady said the treatment was six dollars for ten treatments. Two dollars was paid on account, for which a receipt was given.

Frances Symon, the other policewoman, had a similar experience.

Thereafter a prosecution was begun in the Magistrate's Court on the evidence of these women charging Eifertsen with the crime of practicing medicine without a license. At the conclusion of the prosecution's case a motion was made by the defendant's counsel for a dismissal of the complaint which, after some days' consideration the Magistrate granted and on April second handed down this decision.

"When a person, claiming to be suffering pain, seeks out another and asks for treatment for that condition, well knowing that such person does not claim to be a

regularly licensed physician, as in this case, and such person does treat said applicant by manipulating or rubbing, I can see no violation of the Statute, nor do I believe the legislature intended it to be so regarded. Otherwise, every masseur and chiropractor (so called) in the State would be put out of business.

There was, in this case, no illegal treatment or prescription.

Complaint dismissed—Defendant discharged.

In the writer's opinion the decision was erroneous and, so far as it may be considered a precedent, it is unfortunate. Being a criminal case there is no appeal from this decision and there is nothing further than can be done with the case. As a precedent, however, the opinion of Magistrate Bridges should be no deterrent to the Attorney General in the further prosecution of his commendable campaign, the object of which is to put an end to the unlawful practice of medicine and to stop those who are thus engaged from the practice of their illegal calling.

Since 1907 our statutes have defined the practice of medicine and declared that

"A person practices medicine within the meaning of this article, except as hereinafter stated, who holds himself out as being able to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition, and who shall either offer or undertake, by any means or method, to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition."

This definition was not changed by the enactment of the Webb-Loomis law. The statute further provides that

"Any person who not being then lawfully licensed or authorized to practice medicine within this state shall

(a) Practice or advertise to practice medicine, or

(b) Use in connection with his name any designation tending to imply or designate him as a practitioner of medicine, or

(c) Use the title "doctor" or any abbreviation thereof in connection with his name or with any trade name in the conduct of any occupation or profession involving or pertaining to the public health or the diagnosis or treatment of any human disease, pain, injury, deformity, or physical condition, unless duly authorized by law to use the same, shall be guilty of a misdemeanor."

Whether or not the defendant in this case

used the title "Doctor" within the meaning of the statute is unimportant if he did any act constituting the practice of medicine, that is to say, if he in anywise held himself out "as being able to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition" and if he either offered or undertook "by any means or method" to do the same. It is impossible, we believe, to read the record in this case without reaching the conclusion that the defendant, by his acts, did in fact practice medicine within the meaning of the definition. It was conceded at the trial that he was not a duly registered physician of the State of New York. When he pressed heavily at the base of the right ear of his patient he said "There is nerve pressure there and that is the cause of your headaches in the fore part of your head," this unquestionably was the making of a diagnosis. By telling her what her trouble was and giving her the cause he thereby necessarily "diagnosed" her condition. When he was asked whether or not the pains would respond to chiropractic treatment and he replied "Yes, and chiropractic treatment is just the thing you need to remove the cause of these pains," he thereby "prescribed" for them. When he manipulated his patient's vertebrae upon his table he thereby "treated" her condition. That he was holding himself out "as being able" to do these things was plain enough from the fact that the word "Chiropractor" was written on his door, that his assistant spoke of him as "Doctor", that when personally addressed by the title "Doctor" he responded and that he accepted a fee for his work and arranged to have his patient return for further treatment. If he was not holding himself out "as being able to diagnose, treat, operate or prescribe for any human disease, pain, injury, deformity or physical condition," then what was he doing? For what purpose did he have an office? For what purpose did he have an assistant? For what purpose did he have the name "Chiropractor" on his door and for what purpose did he charge a fee? In the writer's judgment a clear case of a violation of the statute was established.

Our courts have repeatedly decided that one who practices chiropractic as ordinarily understood is in fact practicing medicine and that in so doing, if he is not licensed to practice medicine, he commits a crime. Among the cases which have so decided might be mentioned *People v Allcutt*, 117 App Div 546, *People v Somme*, 120 App Div 21, *People v Mulford*, 140 App Div 716, *People v Ellis*, 162 App Div 288, *People v Shyne*, 242 N Y 176.

So clear is the law upon this subject that the general counsel of the New York State Chiropractic Association, in the writer's presence at one of the hearings upon the Webb-Loomis bill last year, admitted that all those who were

practicing chiropractic were then violating the penal sections of the Public Health Law which makes the unlicensed practice of medicine a crime. The law as it stood at the time of that admission was not changed by the Webb-Loomis amendment.

"It is now the settled policy of the State" (declared Judge Clarke in the *Somme* case), "to hedge admission into the learned professions with strict requirements in order to secure, so far as possible, competent services to patients and clients from physicians and lawyers, and the statutes in regard to admission to the bar, as well as to the practice of medicine, have, to some extent, gone hand in hand."

In the *Ellis* case the defendant was a chiropractor. He was prosecuted for practicing medicine without a license. The prosecution established by a witness whom he had treated that he first "examined her ankle, pronounced the arch as having fallen, massaged the foot and advised a different shoe. On a further visit he manipulated the patient's spine, which, speaking as a spinologist, he pronounced out of alignment in several places. He said he could restore it, but it probably would not stay the first time. He further gave the opinion that the nerves leading to the ankle might be impinged so as to cut off the circulation," declaring that Ellis was guilty of the crime of practicing medicine without a license, the Court further said:

"Rubbing and pressure on the human joints are old therapeutic agents. When accompanied by such attempts at diagnosis as the statement that a patient's pains in the ankle were from the spine having come out of alignment through displaced vertebræ, appellant's acts come within the statutory definition of the practice of medicine."

In the *Shyne* case a woman consulted the defendant "as a chiropractor and not as a regular physician." He claimed to possess the skill requisite for diagnosis and treatment of disease. "As a result of Shyne's manipulation the plaintiff in that case became paralyzed. The treatment which was accorded was described by her as follows: 'I lay down on the couch, face downward, and the support was removed from under my abdomen, and he began working on the spine, and from the neck, way down to the waist and back again. He pressed very hard, so that it made me flinch, especially up through the shoulders. One spot was hurt especially bad. It seemed as if it was his thumbs that he was pressing down hard, and that it hurt, and it made me flinch. And then he took a hold of my head, both sides of my head, and gave it a very violent turn twist one way and then back, which gave a very bad snap, more noticeable

than any of the other treatments. And it hurt.' In the opinion of the Court Judge Lehman said:

"The provisions of the Public Health Law prohibiting the practice of medicine without a license granted upon proof of preliminary training and after examination intended to show adequate knowledge, are of course intended for the protection of the general public against injury which unskilled and unlearned practitioners might cause."

"The defendant in offering to treat the plaintiff held himself out as qualified to give treatment. He must meet the professional standards of skill and care prevailing among those who offer treatment lawfully. If injury follows through failure to meet those standards, the plaintiff may recover. The provisions of the Public Health Law may result in the exclusion from practice of some who are unqualified."

The purpose of the statute is to protect the public against unfounded assumption of skill by one who undertakes to prescribe or treat for disease."

This was the law before the Webb-Loomis bill became a statute. The law as thus defined is still the law.

In his argument for the dismissal of the complaint in the Staten Island case which we are considering, the defendant's counsel quoted from the memorandum of Governor Smith, written at the time he put his signature to the Webb-Loomis bill, the following words:

"This bill, if enacted into law, will not stop anyone from plying any occupation involving the public health who could legally do so before its re-enactment into law. That means that it does not restrict the existing rights of any individual or any group. Although no cult is licensed to practice in this State, it does not stop the practitioners of such cult from practicing the tenets of that cult by any manipulation, or other form of treatment, provided such practice does not involve a violation of the Medical Practice Act or any other section of the Public Health Law, as it existed before the enactment of this bill."

There was not and there should not have been any confusion occasioned by these words. From the foregoing cases we have pointed out that before the enactment of the Webb-Loomis bill no chiropractor unlicensed to practice medicine could "legally" carry on his practice provided any of his acts constituted the practice of medicine as defined by the statute. When Governor Smith declared that the Webb-Loomis bill "does not stop the practitioners" of any cult from practicing their tenets, he

coupled this statement with the significant proviso "*provided such practice does not involve a violation of the Medical Practice Act or any other section of the Public Health Law, as it existed before the enactment of this bill*" But "*before the enactment of this bill,*" as we have seen, the practice of chiropractic repeatedly was held to constitute a violation of the Public Health Law

Whether or not any particular chiropractor escapes the meshes of the law is a matter of public concern, but when a chiropractor escapes under a decision stating that "Otherwise every chiropractor in the State would be put out of business," it is a matter of vital moment to all those who are interested in or charged with any responsibility for the safeguarding of the public health. It is precisely for the very purpose of putting "every chiropractor" who in anywise or by any means "treats, operates or prescribes for any human condition" out of business that our public health laws were placed upon the statute books. "The provisions of the Public Health Law (said the Court of Appeals in the case previously cited) 'prohibiting the practice of medicine without a license granted upon proof of preliminary training and after examination intended to show adequate knowledge, are of course intended for the protection of the general public against injury which unskilled and unlearned practitioners might cause'" And in that case Judge Lehman further said

"The plaintiff employed the defendant to give chiropractic treatment to her for a disease or physical condition. The defendant had no license to practice medicine, yet he held himself out as being able to diagnose and treat disease, and under the provisions of the Public Health Law he was guilty of a misdemeanor."

When, therefore, Magistrate Bridges wrote

"When a person claiming to be suffering pain, seeks out another and asks for treatment for that condition, well knowing that such person does not claim to be a regularly licensed physician, as in this case, and such person does treat said applicant by manipulating or rubbing, I can see no violation of the statute, nor do I believe the legislature intended it to be so regarded."

He enunciated a doctrine which has been repeatedly repudiated by the courts of this State. The fact that the policewoman did not suffer from the pains which she claimed to suffer and which Eifertsen diagnosed and treated is of no importance. What the defendant did and said were the vital facts. If this were not so, then no evidence could be got against the unlawful practitioners of medicine.

The writer's attention was first called to this case by reading the accounts of it in the daily press. The accounts stressed that portion of the Magistrate's opinion following his conclusion that there was no violation of the statute, the words being "Otherwise, every masseur and chiropractor (so called) in this State would be put out of business." A copy of the minutes of the trial was procured and the foregoing statements in regard to what there transpired have been based upon the stenographic minutes of the trial. There is nothing which can now be done about this case, as there is no appeal from a judgment of acquittal in a criminal prosecution. All that can be done is to point out the error of the decision and to urge that the Deputy Attorney General in future cases will continue to exert his fine efforts to combat the unlawful practitioners of medicine.

Especially unfortunate is it that this decision should have been made after the defendant's counsel had presented to the Court this argument

"there is no harm in doing what you can to relieve a man from physical pain. That is not unlawful, even against this strange decision in the Health Law, which was, no doubt in my mind, designed by the medical profession to get rid of their competitors who they could get rid of and their influence as such, as I have observed it, and I know their influence is worked in matters of legislation."

That such an argument should be permitted to prevail in a court of justice is regrettable. It is not the doctors, but the Legislature of this State which has declared that only those who have shown the requisite knowledge and learning through proper examinations should be permitted to practice medicine. The public policy of this State was enacted into laws "intended for the protection of the general public against injury which unskilled and unlearned practitioners might cause." Counsel's argument that "there is no harm in doing what you can to relieve a man from physical pain" may be true as applied to mere assistance given by one individual to another, but where an unlicensed person is doing what he can "to relieve a man from physical pain" as a practice, as a calling, as a profession, maintains an office and exacts and receives fees for "treatments," the law condemns his acts and designates them as crimes. It is not the medical profession that desires "to get rid of their competitors" (if unlicensed practitioners of medicine may be so designated), but it is the people of the State of New York through their laws who have determined to put a stop to their unlawful work by making it a criminal offense to practice medicine without a license.

practicing chiropractic were then violating the penal sections of the Public Health Law which makes the unlicensed practice of medicine a crime. The law as it stood at the time of that admission was not changed by the Webb-Loomis amendment.

"It is now the settled policy of the State" (declared Judge Clarke in the *Somme* case), "to hedge admission into the learned professions with strict requirements in order to secure, so far as possible, competent services to patients and clients from physicians and lawyers, and the statutes in regard to admission to the bar, as well as to the practice of medicine, have, to some extent, gone hand in hand."

In the *Ellis* case the defendant was a chiropractor. He was prosecuted for practicing medicine without a license. The prosecution established by a witness whom he had treated that he first "examined her ankle, pronounced the arch as having fallen, massaged the foot and advised a different shoe. On a further visit he manipulated the patient's spine, which, speaking as a spinologist, he pronounced out of alignment in several places. He said he could restore it, but it probably would not stay the first time. He further gave the opinion that the nerves leading to the ankle might be impinged so as to cut off the circulation," declaring that Ellis was guilty of the crime of practicing medicine without a license, the Court further said:

"Rubbing and pressure on the human joints are old therapeutic agents. When accompanied by such attempts at diagnosis as the statement that a patient's pains in the ankle were from the spine having come out of alignment through displaced vertebrae, appellant's acts come within the statutory definition of the practice of medicine."

In the *Shyne* case a woman consulted the defendant "as a chiropractor and not as a regular physician." He claimed to possess the skill requisite for diagnosis and treatment of disease. "As a result of Shyne's manipulation the plaintiff in that case became paralyzed. The treatment which was accorded was described by her as follows: 'I lay down on the couch, face downward, and the support was removed from under my abdomen, and he began working on the spine, and from the neck, way down to the waist and back again. He pressed very hard, so that it made me flinch, especially up through the shoulders. One spot was hurt especially bad. It seemed as if it was his thumbs that he was pressing down hard, and that it hurt, and it made me flinch. And then he took a hold of my head, both sides of my head, and gave it a very violent turn twist one way and then back, which gave a very bad snap, more noticeable

than any of the other treatments. And it hurt.'" In the opinion of the Court Judge Lehman said:

"The provisions of the Public Health Law prohibiting the practice of medicine without a license granted upon proof of preliminary training and after examination intended to show adequate knowledge, are of course intended for the protection of the general public against injury which unskilled and unlearned practitioners might cause."

"The defendant in offering to treat the plaintiff held himself out as qualified to give treatment. # NEWS NOTES

## THE ANNUAL MEETING

Arrangements are about completed for the committees have perfected the plans for the Annual Meeting of the Medical Society of the assemblies and meetings. All that now remains to do is that the members and their wives shall take the train for the Falls and doctors and their companions, and the various spend a pleasant four days at the meeting.

## THE COMMERCIAL EXHIBITS

The physical equipment of a modern doctor's office must necessarily excel that required a generation ago to an extent that equals the progress made in the science and art of medical practice. A doctor must have tools with which to work, and these are supplied by commercial houses.

Manufacturers and distributors of medical supplies are the welcome friends and associates of physicians. They are always willing to assist the doctor in devising his instruments, publishing his books, preparing attractive med-

icines, and assisting him in satisfying his patients.

The Medical Society of the State of New York recognizes the debt of the profession to its business associates by arranging a commercial exhibit and giving it a prominent place in the program of the annual meeting.

It will be of mutual advantage to both the physicians and the exhibitors if the doctors will linger at the booths, consult the demonstrators, and show their friendliness to those on whom they depend for their physical equipment.

## THE INDIVIDUAL EXHIBITORS

Booth 21—The Abbott Laboratories, Chicago, Illinois, will exhibit drugs and pharmaceuticals. Be sure to see the new Council-passed Abbott item—*Ephedrine Hydrochloride*—the alkaloid of the Chinese drug, Ma-Huang, used extensively in the treatment of asthma, etc. Also, have you any questions on products such as *Butesin Picrate Ointment*, *Neonal*, *Metaphen*, and other Abbott and Dermatological Research Laboratories' products of quality and dependability?

Booth 12—Becton, Dickinson & Company, Rutherford, N. J., expects to have a complete line on display and its representatives will be glad to show the profession the latest developments in syringes, needles, bandages, thermometers, etc.

Of particular interest will be the new *Armored B-D Manometer* which is practically unbreakable and which has a replacement feature of particular merit.

Booth 15—Frank S. Betz Company, Hammond, Indiana, will have on display a new improved *Murphy Hydraulic Operating Table* and a complete line of the *Krome Plate Rust-Resisting Instruments*. Our Exhibit will be given over entirely to the demonstration of new instruments and equipment that have been developed since the last convention, and will be in charge of Mr. Theodore Bailin and Mr. Paul Ross.

Booth 10—P. Blakiston's Son & Company, Philadelphia, will show publications. Among the many new books of the company, the new Deaver,—"The Surgical Anatomy of the Human Body," stands out as one of the leading contributions that have been made to medical literature in recent years. Other important new books are Edgar's "Obstetrics," Strecker & Meyers' "Clinical Neurology," four new volumes in the "Recent Advance" Series, Stoddard's "Mind and its Disorders," etc.

Booth 24—Cameron's Surgical Specialty Company of Chicago and New York City has a trained representative at Booth 24 where will be found the most modern electric-lighted *Diagnostic and Operating Equipment* in the world. There will also be exhibited the now famous 2-lb. *Cantery Outfit* using solid platinum tips. Many new instruments will be shown, including the new *Otoscope*, *Nasoscope*, *Procto-sigmoidoscope*, *Urethroscope*, *Anoscope*, *Skencoscope*, *Mouth-gag*, and *Retino-ophthalmoscope*.

Booth 20—R. B. Davis Company, Hoboken, N. J., say that "The Fountain of Youth" has been found at last, in fact it is at your very door. One of the newest and best of all health aids—*Cocomalt*—will be featured at the meeting of the Medical Society of the State of New York, Niagara Falls, New York. When you visit the *Cocomalt* booth, look into the mirror

and you will see the health aids translated in terms of foods, rest and cleanliness. Carrots will give color to your cheek, whole grain cereals a finish to your skin, beets will add color to your lips, etc., while one of the best and newest of all—*Cocomalt*—will put youth into your being and add years to your life.

*Cocomalt* has gone to nature, not the chemist for its nutritive value as well as its delicious flavor.

Booth 9—Deshell Laboratories, Inc., Chicago, Illinois, expect that the preference for an emulsion of mineral oil for intestinal lubrication will undoubtedly create much interest in its *Petrolagar* Exhibit.

At this exhibit, the Deshell Laboratories, Inc., will have some interesting material to demonstrate, in a graphic manner, why the emulsion of mineral oil and agar is superior as an intestinal lubricant to the plain oil.

The representatives in charge of the *Petrolagar* exhibit will have important data on the clinical application of the various types of *Petrolagar*, their use in spastic and atonic constipation, and in the modification of the Sippy method of treating gastric ulcer.

Booth 4—H. T. Dewey & Sons Company, New York, will exhibit grape juice products and compounds. For seventy years this house has been noted for the excellence of its products. Founded in 1857 by Hiram T. Dewey, who was a pioneer in wine making in America, the firm has developed medicinal products of which grape juice is a constituent. It will exhibit *Dewey's Emulsion of Cod liver oil*, *port wine* and *Irish moss*—a tonic easy to take and digest.

*Dew-tonic* and port will also be shown. This product is sold directly to the consumer.

Dewey's wine-grape juice will also be shown. This is the pure juice of the white or red wine grape cold pressed. No preservatives or coloring matter is used.

Booth 7—The De Vilbiss Company, Toledo, Ohio, will display its well-known line of *nose and throat sprays*, *nebulizers*, *steam vaporizers*, etc., for office and prescription purposes.

Booth 29—Dry Milk Company, New York, pioneers in the manufacture of a special quality of dry milk for infants and invalids, will exhibit *Dryco*, also *Protolac*, a calcium caseinate. As usual, it will distribute useful souvenirs and, more important, will show a new product, a very marked development in the increase of the nutritional properties of milk.

Booth 8—H. G. Fischer & Company, Inc., Chicago, will exhibit a most complete line of *physical therapy apparatus and electrodes*, a distinctly new and extremely powerful *diathermy cabinet*, a *tissue cutting apparatus*, a low voltage

and wave current generator which is remarkably smooth in action, and its latest *radiant therapy lamp*, as well as quartz *ultraviolet apparatus*

Visitors will find the Fischer line of supplies and accessories unexcelled anywhere. Some new electrodes will be shown for the first time at this meeting.

**Booth 17**—The Hanovia Chemical & Mfg Company of Newark, New Jersey, will exhibit, as usual, its entire quartz mercury anode type quartz lamps, the *Alpine Sun Lamp*, the *Kro-mayer Lamp* and the Luxor model of the *Alpine Sun Lamp*. Together with these, they will have on display two different models of lamps, especially designed for particular needs, embodying certain refinements.

Competent members of the Hanovia Staff will be on hand to demonstrate and explain in detail any of the lamp's workings. A cordial welcome is extended to all physicians attending the meeting.

**Booth 16**—The Harold Surgical Corporation, New York, will exhibit some recent developments in electro-therapeutics including *Tropico Sun Twin Arc Violet Lamp*, which sells for only \$200.00, *Multotherm*, a heavy duty diathermy apparatus with the high frequency cutting current (radio knife), *Portatherm*, a startling value in portable diathermy apparatus, *Bierman High Frequency Electro Surgical Hemorrhoid Clamp* which makes hemorrhoidectomy a bloodless office procedure.

**Booth 28**—Horlick's Malted Milk Corporation of Racine, Wisconsin, invites the attention of all present at the annual meeting of the Medical Society of the State of New York to its Booth No. 28, where there will be on display the universally known *Horlick's*, the original *Malted Milk*, in powder and tablet form, and also *Horlick's Chocolate Flavored Malted Milk*.

The representatives in attendance will be pleased to explain the advantages of these various products to the medical profession, and will welcome their inquiries and discussions. The *Dumore Electric Mixer* will be demonstrated, and samples and literature will be supplied.

**Booth 30**—The Kalak Water Company of New York will again be present with an exhibit, and physicians who desire a delightful and refreshing drink during the meeting are invited to call at the exhibit. A representative will be present and will be glad to serve you.

**Booths 5 and 6**—The K. & B. Electrical Equipment Company, Inc., of New York, Rochester, and Buffalo, distributors of the *Kelley-Koett Electrical apparatus* for over ten years, will exhibit that firm's latest productions in *X-ray equipment*. It will also show the firm's *diathermia machines*, and *heat or infra red lamps*, *Hanovia Quartz Lamps*, and other physical therapy equipment.

**Booth 25**—The Kimberly-Clark Company, Inc., Niagara Falls, will exhibit *sanitary specialties*, and particularly *Kotex*.

**Booth 26**—Merrell-Soule Company, Syracuse, N. Y., will exhibit *Klim*, Merrell-Soule *Powdered Protein Milk*, Merrell-Soule *Powdered Whole Lactic Acid Milk* and allied products which constitute its group of infant breeding products.

*Klim* will be served to visiting physicians so that they may judge as to its flavor, and the attendants will be glad to answer any questions regarding the scientific background and clinical success of each product.

**Booth 3**—The Mutual Pharmacal Company, Syracuse, N. Y., will display products of its laboratory. These products represent the highest achievement in pharmaceutical practice and are carefully tested and assayed to meet the requirements of discriminating physicians. A cordial invitation is extended to physicians to visit the booth.

**Booth 2**—Pfau's American Instrument Company, New York, will exhibit a full line of *New anatomic specimens and teaching material*, the latest *ear, nose and throat instruments*, *specialties for plastic surgery and nasal correction*.

Special features are: Set of specimens showing Dr. Halle's various sinus operations and different kinds of mastoid operations.

Tanned nose specimen with movable septum and with new arrangement of the sections, Atkinson's latest directoscope. The latest patterns of Pfau's well-known cutting and punching instruments.

**Booth 14**—James Picker, Inc., of New York City will be represented at the forthcoming meeting in Niagara Falls by an exhibit of precision *X-ray and Physical Therapy Equipment* which will introduce a number of the latest developments in the field.

The X-ray exhibit will include equipment of special interest to the general practitioner. Mr. Walter Steinkamp of the Rochester office of this firm will be in charge of the demonstration.

**Booth 1**—Sanborn Company, Cambridge, Mass., will exhibit their standard metabolism apparatus and the portable Sanborn Electrocardiograf. New features for Metabolism Testing include the White Grafic and our special white enamel, transportable table. Doctors and technicians are cordially invited to see demonstrations of apparatus and testing methods.

**Booth 13**—W. B. Saunders Company, Medical Publishers, Philadelphia and London, will exhibit their entire line of some 250 titles. Of particular importance are a great number of new books and new editions including Cecil's *Textbook of Medicine*, Ford's *Bacteriology*, Wechsler's *Clinical Neurology*, Young's *Practice of Urology*, Rehfuess' *Diagnosis and Treatment of Diseases of*

*the Stomach*, Crohm's *Diseases of the Stomach*, Wood and Rowell's *Health Supervision and Medical Inspection of Schools*, the new *Mayo Clinic Volume*, Kolmer's *Chemotherapy*, Stokes' *Clinical Syphilology*, an entirely rewritten edition of Griffith and Mitchell's *Pediatrics*, Morse's *Pediatrics*, Arny's *Pharmacy* and Sollmann's *Pharmacology*, both revised in accordance with the new Pharmacopeia, 10th edition of Scudder's *Fractures*, 2nd edition of Stevens' *Practice of Medicine*. As this list of new books and new editions indicates those attending the convention will find among the Saunders titles a number of books of practical value whether they be general practitioners, surgeons or specialists.

Booth 18—C M Sorensen Company, Long Island City, N Y, will exhibit and demonstrate the much talked about DeLuxe Equipment, the popular hospital *anaesthesia and operating outfit No 425*, and the *adjusto combination No 454*, the favorite of all adjusto outfits. The balance of the exhibit will be made up of specialists chairs and stools.

Booth 19—The Spirella Company, Niagara Falls, N Y, will show its corsets and supporting apparatus. Physicians and Surgeons who are interested in obstetrics, pre-natal and post-natal support, ptosis and post-operative garments, spinal support and poise correction should visit the Spirella booth where Spirella garments will be exhibited, and Spirella literature may be obtained. Group or individual demonstrations will be given on living models. Private demonstration room.

Booth 22—The Tailby-Nason Company of Boston, producers of Nason's Palatable Cod Liver Oil, will have a display of their "good tasting" medicinal cod liver oil with pictures showing the conditions under which it is produced. An important part of the demonstration will be white rats used in testing for vitamin activity.

Booth 27—The George Tiemann Company, New York, calls attention to its surgical instruments and appliances, among which will be many new items. Lamps of various kinds, both light-

ing and therapeutic, will also be displayed at its booth. It will also be glad to have doctors and hospitals register for its Centennial Catalogue which will be sent prepaid on receipt of request.

Booth 11—The Victor X-ray Corporation, Chicago, will feature its line of *Physical Therapy apparatus*, including the new portable *Vario-Frequency Diathermy apparatus*, with a capacity of 4,000 ma over a selective frequency range of from 500 to 2,000 kilocycles, the *Wantz Multiple*

Prospect House in which the exhibits are held.

*Wave Generator*, for the production of Galvanic, surging galvanic and sinusoidal currents, air and water-cooled *Ultraviolet Quartz Lamps*, and *Phototherapy Lamps*.

The trained representatives in charge of the Victor booths will cheerfully assist you in solving your technical problems involving either physical therapy or X-ray apparatus.

Booth 23—The Wappler Electric Company, Long Island City, N Y, will exhibit its line of electro-therapeutic apparatus, among which will be the *Moner*—the small, silent, powerful apparatus, the New Model B *Electrotherm* and the *Wappler Sine Wave Generator*. A selection of *Cystoscopes* will also be shown in the Wappler booth.

## A CORRECTION

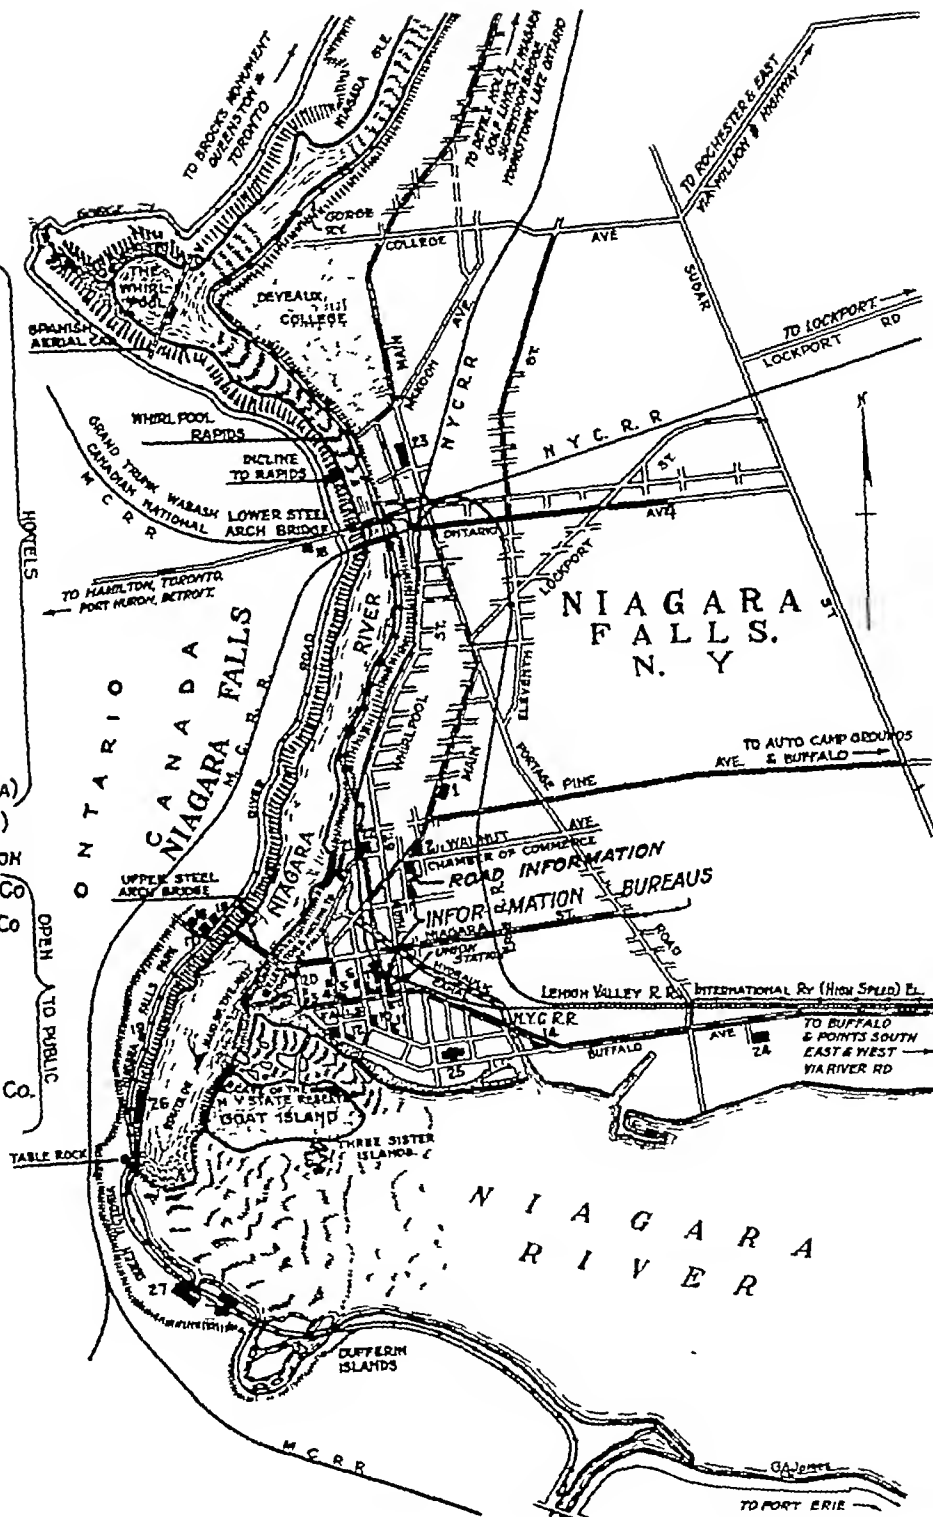

The article entitled "The Annual Meeting" on page 372 of the April first issue of this JOURNAL, was in reality two articles, one sponsored by Dr. Frederick J. Schnell, Chairman of the Committee on Arrangements, and the other by Mr. G. L. Bowe, Manager of the Convention and Publicity Department of the Chamber of Commerce of Niagara Falls. The two articles were printed as one and so Mr.

Bowe's name appears as if he were responsible for the official meetings of the Society.

Why did the editor fall into this sin of omission? He has no excuse to offer. He trusts that the readers will assume the attitude of President Roosevelt when he said that he would excuse a man for making a mistake, but he would not excuse him for making the same mistake twice.

## HOW TO SEE NIAGARA FALLS

The Falls of Niagara are peculiarly well situated for being seen from many points of view. A visitor having only a few hours is tempted to linger at a single place and there study the details, but in doing so he is likely to miss the grandeur of the Falls, the Rapids and the Gorge, all of which should be seen in order to know Niagara. The course usually followed by the sightseer is to go first to Goat Island and spend so much time there—profitably to be sure—that he misses some of the most important other aspects of the views. In order to get the maximum impressions in the briefest time, the following course is advised.

Go first to the Maid-of-the-Mist landing and sail up to the Falls. This will give one an impression of the stupendous height and volume of the Falls—something that one misses almost entirely when he views them from a distance.

Second, land on the Canadian side and walk

up to the Horseshoe Falls. The distance is about half a mile and all the while one is facing the Falls.

Third, take the trolley at the Horseshoe Falls and ride down along the upper rim of the Gorge. This gives one an idea of the depth and enormous size of the chasm that has been carved in the rock by the river.

Fourth, cross the river at Lewiston and ride back along the water's edge, at the bottom of the Gorge. This will afford a near view of the rapids.

Lastly, go to Goat Island, and enjoy the details of the exquisite view of its rocks and rapids.

This order of view starts at the very outset to impress one with a sense of the overwhelming grandeur of the Falls and Gorge—something which visitors miss almost entirely when they fail to take the Maid-of-the-Mist trip, or ride along the rim of the Gorge.

HORSESHOE FALLS

## WOMEN'S MEDICAL SOCIETY OF NEW YORK STATE

The annual meeting of the Women's Medical Society of New York State will be held at the Hotel Niagara, Niagara Falls, N. Y., Tuesday morning, May 10, 1927. The general topic will be "Preventive Medicine."

In place of the usual formal banquet on the night of the meeting, there will be a luncheon Tuesday noon that will partake of the nature

of a Round Table, with three minute responses to Roll Call.

Dr. Zella White Stewart, a prominent allergist from Iowa, will speak on "Asthma and Hay Fever", Dr. Schroder on "Immunity in Scarlet Fever", Dr. Rosalie S. Morton, who has just returned from South Africa, will speak on "Exotic Medicine", Dr. Van Alstyne on

"The Use of the Alpine Sun Lamp in Diseases of the Skin," and Dr. Buck on "X-Ray Treatment of Fibroids"

We desire reports from Councillors of the District Branches, and recommendations in regard to greater activity of our members at the District Meetings. There will be a report on Gotham Hospital and other reports interesting to women physicians.

A Council Meeting will be held from five to six o'clock, Monday, May 9th, at the same place. We hope that the women physicians throughout the State will take a holiday at the Falls and join the Council at an informal dinner, at six o'clock, on Monday evening.

Make your reservations early, and plan to remain for the meetings of the New York State Medical Society.

## COURT HEARINGS IN THE COMMITMENT OF THE INSANE

The following letter will be of interest to all physicians who deal with commitments of the insane.

STATE OF NEW YORK  
Department of Mental Hygiene  
Albany, N. Y.

April 7, 1927

Dear Mr. Editor:

I am very glad to have your letter of April 6th, referring to an article in the *New York Sun* of April 4th, which described a scene in a Brooklyn court where twenty insane patients were present awaiting commitment. Your letter gives me an opportunity to comment on the practices of Brooklyn judges.

The commitment of a mentally sick person is discretionary with the court. It can accept the affidavits presented or can require further proof. For several months Brooklyn judges have insisted on the actual presence of the patients. Nowhere else is this thought necessary, but they have required it and the courts' directions had to be obeyed. The rule is open to many objections. It is unnecessary, humiliating to patients, and the effect of bringing

sick persons to court before they can have the relief which the State affords is detrimental to the well being of those so produced. I assume the reason behind the rule is the thought that sane people are being sent to State hospitals. That topic furnished many a plot for the mid-Victorian novels, but it does not exist in New York State today, for with the great overcrowding of its hospitals, every effort is being made to prevent the admission and to release promptly every person capable of care in the community.

There has been no change in the mental hygiene law, although each year a jury trial bill is introduced and the Department actively opposes the enactment into law of any measure which will make appearance in court a necessary preliminary to admission to a hospital. It cannot be too strongly urged that mental illness is not a crime, that presence in court should not be required. It is barbarous, inhuman, and cruel, and your assistance in combating the practice will be greatly appreciated.

Sincerely yours,

FREDERICK W. PARSONS, M.D.  
Commissioner

---

## THE INTERNATIONAL MEDICAL CLUB OF NEW YORK

An organization called the International Medical Club of New York, which has recently been formed, gave its inaugural dinner on April 12, in the New York Academy of Medicine. Its president, Dr. Samuel J. Kopetzky, in stating the objects of the Society, said:

"Theoretically science has always been international, but differences of race and language have set up barriers and limited the diffusion of knowledge and discovery to class rooms and the pages of medical journals. The objects of the International Medical Club are to wipe out some of these barriers, through establishing contact with similar clubs in foreign countries, through the promotion of social and medical contacts between the for-

eign language and medical societies in the United States and the American medical profession, through organizing receptions for visiting physicians and providing a forum for lectures on international medical subjects, and through facilitating the interchange of courtesies in clinics and institutions.

"The International Medical Club is the first of a string to be established in America and abroad. Several are already being organized throughout this country. Virtually every nationality is represented in the parent body."

The speakers at the dinner included Baron de Cartier de Marchienne, the Belgian Ambassador, M. Gaston Liebert, the French Minister to Cuba, Dr. Antonio Stella, representing

the Italian Consul General, and Senor Rafael de Casares, the Spanish Consul General

The officers of the Club are

Dr Samuel J Kopetzky, President, Dr Pol Coryllos, 1st Vice-President, Dr Jacques Malinjak, 2nd Vice-President, Dr William S Bainbridge, 3rd Vice-President, Dr Frank R Herriman, Secretary, Dr Jose A Lopez, Treasurer, Dr Wolff Freudenthal, Historian

The directors are

Dr Henry H Forbes, Dr Max A Goldzicher, Dr Thomas J Harris, Dr I Seth Hirsch, Dr Sergius M Ingerman, Dr Gaston Labat, Dr Leon T LeWald, Dr Emanuel Libman, Dr P M Marafioti, Dr Michael Os nato, Dr Wendell C Phillips, Dr Frederick P Reynolds, Dr William Sharpe, Dr Ervin Torok, Dr Manuel U Troncoso, Dr George Gray Ward, Dr Linsly R Williams

## ERIE COUNTY MEDICAL SOCIETY

Plans for the promotion of post-graduate medical instruction in Erie County were immeasurably advanced at the regular meeting of the Medical Society of the County of Erie, held March 21, 1927, in Alumni Hall, University of Buffalo, when the Society voted to accept an offer made by the Board of Managers of the Buffalo City Hospital to place at the disposal of the Society for graduate teaching purposes the clinical facilities of the outpatient department of the Buffalo City Hospital.

The offer was accepted with the proviso that the clinics be conducted under the direction of a staff chosen by a committee appointed by the President, and that committee be authorized to solicit information of what branch of medicine the members wish to engage in, and be authorized to carry into effect the teaching facilities. This means that the scientific resources of this great institution will be available to members of the Society as continuation students and the courses of instruction will be in charge of capable teachers.

For the March meeting President W Warren Britt had invited the superintendents of all hospitals to present to the Society the advantages they have to offer for clinical instruction, in order that the members might have an opportunity to entertain and discuss the invitations and adopt definite plans agreeable to the management and staffs of these institutions. Representatives from the various general hospitals expressed a hearty willingness

to co-operate in the development of the movement to increase the diffusion of medical knowledge and enable the general practitioner to do better work by attending clinics, staff meetings and pathological conferences. The superintendents of State Hospitals in Buffalo and Gowanda extended liberal invitations to the members of the Society who are interested in the study of mental diseases to make use of the facilities of these institutions.

The growing interest in continuation medical study manifested by physicians in Erie County is evidenced by increased attendance at meetings of the Society devoted to that subject. The members present at the March meeting exceeded the combined attendance of the January and February meetings.

Courses in post-graduate instruction were adopted by this Society in 1926, under the presidency of Dr Robert E DeCeu. A course of six lectures in Pediatrics was given at the Children's Hospital. A committee was appointed to make a survey of local hospital facilities for clinical instruction. The report of the committee set forth detailed information relating to the resources of this great medical center in Western New York. The report was published in pamphlet form by the Society last January, and a copy mailed to every physician in the Eighth District Branch.

E P ORVIS, M D Secretary  
Medical Society, County of Erie

# THE DAILY PRESS

## SPONTANEOUS GENERATION

The modern science of medicine and surgery is founded on the law of "all life from life." Physicians of the present day have difficulty in comprehending the state of mind when the learned, both scientists and theologians, believed in the spontaneous generation of living things from dead matter,—abiogenesis, as was called. The *New York Herald-Tribune* of April 11 comments on the work of the observer to whom is ascribed the honor of being the first to demonstrate the parentage of these living things whose origin had hitherto been ascribed to putrifying matter. An editorial entitled "Epoch-Making Worms," reads

"The first man who wrote the birth certificate of a worm, thereby to win undying fame, has been honored this year in Italy by the celebration of the 300th anniversary of his birth. His name was Francesco Redi. He it was who proved that worms had ancestries, respectable or otherwise, and were not merely created out of nothing at all by some mysterious power of the forces of life.

"Redi's was perhaps the most important of all

discoveries in the sciences of life, for it opened the way to everything that has followed, even to the revolutionary discoveries of Pasteur concerning the germ theory of disease. Lacking microscopes which could trace every stage in the lives of the small meat worms, as we can do today, Redi made experiments with what he had. He placed portions of meat in screened jars, so that air could enter but flies could not. In this protected meat no worms appeared. But persuading the flies to lay their eggs on the screens themselves, above the attractive bits of meat, he proved that it was from these eggs that the worms came, worms which we now know to be the larval stage in the life history of the flies. Among the great landmarks of science these discoveries of Redi constitute one of which his countrymen in Italy have every right to be proud."

Redi was a famous poet who also made many exact observations in biology. He observed, for example, minute parasites in the intestines of crabs. Yet it is strange that the encyclopedia Britannica does not devote an article to him, although a few references to his work may be found in the index.

## THE SLAYER OF DR PENDOLA

A verdict of guilty of first degree murder has been rendered against Frank Caruso of Brooklyn, who killed Dr. Casper Pendola on February 12. The doctor had injected antitoxin into Caruso's child who was dying with diphtheria. Death soon followed, and for it Caruso took the doctor's life.

The *New York Herald-Tribune* of April 12 prints a half column of letters protesting against the infliction of the death penalty on the ground that the murder was not premeditated, but was the result of temporary insanity. The letters reveal an attitude of sentimentalism on which the criminal relies to escape the full legal punishment for his crime. The writers of the letters seem to think they have made a new discovery in psychology, and that "Temporary insanity" is a mental disease for which the patient is not responsible any more than he is responsible for mania during an attack of cerebro-spinal meningitis.

It is commonplace to say that anger, or other sudden violent emotion is temporary insanity. Granting that a person's judgment fails him at

a critical time, and that while in that state he commits a heinous crime, what should society do to protect itself from other outbreaks? If a man who can meet ordinary situations with calmness and judgment, cannot meet extraordinary situations, that man may be a serious menace to society. It is of course a grave question whether or not a criminal in that state should be put to death,—if indeed any person should,—but there can be no doubt regarding the duty of society to place that man under such restraint that never again could he have the occasion or the opportunity to repeat his crime.

One letter says "The acquittal or pardon of Caruso on the ground of temporary insanity would be no reflection upon the medical profession." This is where the writer is entirely wrong, for he advocates that the criminal be set entirely free and completely absolved from his crime. Physicians do not believe Caruso should be set free. They believe that he should be put under restraint for life, and that temporary insanity has no place in diagnosis.

# OUR NEIGHBORS

## MEDICAL PRACTICE ONE HUNDRED YEARS AGO

The Practice of Medicine a century ago had its unpleasant side, especially for the younger doctors. The older practitioners were intensely jealous of the new-comers, and often refused to have anything to do with them, and frequently even slandered them. There was something of justification in this attitude, for in the absence of clinics and medical journals, almost the only available method by which a doctor could make progress in his art was by means of his own experience, and that of course he was unwilling to share with anyone else. He might publish it in a medical journal for the benefit of his medical brethren, who lived a hundred miles away, but he was not willing to share it with his brother doctor in the same town.

*The Journal of the Michigan State Medical Society* for April contains letters written by Dr. D. L. Porter, in 1828, while he was trying to establish a practice in Pontiac, Michigan. On December 29, 1828, he wrote —

"I really wish that you could have seen our Christmas celebration in this town. Of all motly assemblies! You never saw the like. It is general holiday. The first thing was to call out the sharp shooters to wreak their vengeance on the turkeys. They were set up at 25 rods, sixpence a shot at arms and there were some of the greatest marksmen I ever saw. One man bought twelve shots and the contract was that if he did not strike the head or neck, even though he killed the turkey, it was to be considered as lost to him. He struck the neck nine times, the head once and the body twice. Many of the marksmen killed at every shot. After shooting they went to gambling and drinking, singing and dancing. You can form no conception of the scrape they had. It is utterly out of my power to give even a faint outline of the proceedings. The scrape was kept up until Sunday night. I thought that many must have killed themselves but to my amazement there was not an accident, nor a single dead set battle, nor any violence though I think that many will feel the effects of it for months if not for life. Many lost a great deal of money. One young man set up his farm at rush for 500 dollars and took a share in. He won it back and set it up again for one-half and lost that and before night, every cent he had in the world. Such are the people who are pioneers in a new country. Slaves alike to the soil and to their passions. They are, however, a transient class. They

soon fall a sacrifice to their excesses or when broke down retreat to the western wilderness again to gain and again to lose, there being no such thing as reformation.

"I have had but little business since I wrote last. One call which ought to have stood me twenty dollars cost me four or five besides my time and labor. I was called in council to Hoxies Settlement 35 miles northeast of here in Macomb County with Doctor Janning, a graduate of Burlington in the days of Smith and Porter. It was a case of typhus and the man died 12 hours after I got there. I was detained one day by my horse being sick, the man who died did not leave enough to bury him and I had the pleasure of being gone three days, paying one dollar a day for a horse and keeping him during that time.

"Doctor Thompson has been very particular in warning everybody against me as a quack and swindler. The first I have disproved by my papers and practice, the second I must leave to time to develop. I am determined to stick to Pontiac through evil and through good reports. I know I can give the Doctor a pull as he is most heartily hated. One man, an enemy to Thompson and in my esteem no friend to me, offers to let me have one hundred and fifty dollars if I will give him my judgment bond for one hundred and fifty with interest and an execution on my horse and books and medicine. I have thanked him for his kindness as I ought but have concluded to wait patiently until spring. My stock of medicine will last me several months and LeRoy will accommodate me with board at his own risk but is so far prejudiced by Thompson that he will go no farther. I have paid the \$20 rent on an office for six months in advance and what money I have will pay my horse hire until I shall be able to get a horse. Twelve families have given me their public pledge that they will give their business for one year at least, but I have to take my pay in grain or dicker as it is called, a year from this time. Which is the only season for paying debts in this country.

"Thompson having quarreled with all the neighboring physicians, they have one and all pledged themselves not to call on him in council and have proposed to me to act as consulting physician, which I have engaged to do."

On January 1, 1830, he wrote

"A Happy New Year to all of you. I was

(Continued from page 512)

woke about an hour since by the yell at my door of some ragged, wild looking urchins, of 'A Happy New Year, Doctor' I got to the door and thanked them, they were not satisfied with that, however, and one of them said that dad had told him that I was a Dutch man and had oceans of hot punch and cake and his object in calling was to partake of the good things and he would be damned if he did not have some and Dick wanted some too' I found that I could not be rid of them by fair means so I resorted to the earnest and gave them a chance either to clear out take some yalop or a cowhiding To my utter amazement one chose the yalop (not knowing what it was) I mixed it with some water he ate some but concluded he had no 'further occasion, decamped with a yell and followed by his companions who promised not to trouble me for devil's milk again in a hurry

"Do you recollect my expressing a wish to have the ague for the sake of experiment I'm satisfied for I have it with a vengeance every other day, at precisely twelve o'clock It is not like our ague It makes me shak like vengeance, but does not last over two or three hours when I am able to resume my books or ride or whatever else I feel disposed for the moment to do The chill is very severe but the other stages amount to nothing and when over I feel no bad effects except a general soreness for a few hours It is probably occasioned by the very warm weather and the draining the mill pond to repair the dam Almost every person in the village has it, but they never do anything for it as cold weather will stop it I have had four fits and expect one today I shall leave it to take its course for a few days longer when I shall have to try calomel for a few days The ague is looked for regularly and receives little attention from the inhabitants

"Thompson and me closed accounts yesterday, he said that it was always good policy to work off the bile at the end of the year He raved like a mad man and I laughed at him I found afterwards that it was his determination to quarrel with me and then make peace and form a partnership I will see him as he wished me, d'nd first A partnership on no terms shall be formed now, as he has acted like a scoundrel By his violent and unmanly conduct he has long ago excited the contempt and hatred of many, and his present course is far from a soothing one I shall eventually root him out root and branch, if he does not go to his majesty on a whiskey barrel first The greatest misfortune I have to contend against is the coming in here after two real scoundrels had to decamp They both

(Continued on page 515—Adv. XIII)

(Continued from page 514)

did well for a year or two but became dissipated and shaved all their creditors and friends out of their demands. The people still feel sore and are very much on their guard and their fears are kept alive by the bold assertions of Thompson. The course he pursues is the very one which I could have wished, as I might not have been known for a good while, but now I am known personally, or by report by every person within ten miles of this."

On March 1, 1830, he paid his respects to the women of Michigan in the following terms:

"I have not yet seen the young lady in the territory whom I would take for better or worse for her weight in gold. The majority are lamentably deficient in either natural or acquired graces. In the rich and harmonious vocabulary of the Kentuckian, they are half horses, half alligator and the rest made up of the well known properties of the wild cat and snapping turtle. There are many who would be ornaments to any society if they had the advantages common in our own section of the country. You must therefore select one for me in old Saratoga against the time that you think it would be best for me to play the fool."

Dr Porter seemed to prosper in his practice for on March 1, 1830, he wrote:

"Business is improving. In the last month I have charged \$45 00. Ten of which is good for nothing. I have entered into a partnership with Mr Beach in the druggist business."

Two months later he wrote:

"Since my last letter there has been but little sickness until within a few days. My charges since the 23rd of April have been \$31 54 and I have two patients to visit out of town, besides three that come to the office. Great fears are entertained throughout the territory (thus of course must not be hinted out of our own family as it might deter emigrants), that it will be the most sickly season that we have had for some years. I must confess that from present appearances it will be the case, if my suspicion should prove correct I have no apprehensions for myself on the score of business."

On August 10 of the same year he wrote:

"Black Bill," as he is called, alias Doctor T, continues savage because I would not be salivated or die, nor salivate or kill any of my patients, which, thank God, we have not found necessary in a single case, as yet, whereas he has salivated all of his and out of seven cases of fever he has lost three. In his wrath he has opened an opposition druggist shop. He damned Judge LeRoy the other day for introducing me here, as since the sickly season

(Continued on page 516—adv xxiv)

## SUPPOSE YOU Had a Patient

High-strung, nervous, erratic

or

Listless, dull, phlegmatic

Would you treat her confidently as hyper or hypo-thyroid, or would you be better satisfied to actually convict or eliminate the thyroid as a governing factor in the case?

These are typical examples of the many instances in which the Metabolism Test is a valuable guide in differential diagnosis. Hyper-thyroidism and Tuberculosis, or Myxedema and Eczema often present clinical pictures so similar that the Basal Metabolic Rate is a definite aid in the correct study and treatment of the case.

### Metabolism Tests Are Simple

You or your office assistant can test Metabolism quickly easily and accurately in your own office or at a patient's home with the Sanborn Graphic Metabolism Tester.

It's simple to use, portable and scientifically precise. A Kymograph built right into the Graphic, automatically records every detail of the test on a chart, showing the result in visible permanent form.

Fifteen minutes complete a Metabolism Test with the Graphic. Twenty cents more than covers accessory costs per test! (You receive supplies for the first 40 tests when the Graphic arrives.)

Because it is simplified, economical and proven accurate, 1,200 doctors have already chosen the Sanborn Graphic for their metabolism tests.

It's worth your while to ask for our Illustrated Booklet

commenced he had not charged \$300, whereas ours since the second of June amounts to about \$500. Business in consequence of the rain has not been as good for the last week or ten days our daily charges average from 8 to 12 dollars—during our harvest time it would sometimes go as high as 30 dollars

'You enquire what are the legal qualifications of a physician in this country?' They are to pass an examination before the censors of the territorial society and before they can proceed to do that he must show the degrees of M.D., a license or a certificate of study for three years of a liberal education, four if not. Those presenting a degree seldom have much trouble in passing but not to the licentiate of the foreign student as but little mercy is shown to either. The cost is about \$12 if you join the Society, which is expected. Encourage none to come, as 99 out of a hundred will be disappointed as there is not a Pontiac at every door. Our profession is overstocked in the territory and this summer more than 4 have gone away in disgust

'A physician, to obtain a support, must for months in the year undergo everything but death. You must go almost altogether on horse-back and contrive every way to save distance by following Indian trails, or for want of these cutting through the woods to save distance frequently 30 to 50 miles per day and still have to go from morning to night. We think nothing of riding 15, 30 and 40 miles to see a patient sometimes 80 to Saginaw (as the settlement has not and cannot support a physician)'

## MEDICAL CO-OPERATION WITH LAY ORGANIZATIONS

The peculiar field of lay organizations engaged in public health is that of educating the public in medical subjects. The relations of medical to lay organizations is discussed in the following editorial in the *Illinois Medical Journal* for March

'Co-operation of educational committees and lay organizations must of necessity be guided by some sense of ethics. It would seem requisite at the outset of an intensive campaign to give health information to the public, that no errors should be made as to which groups of lay educators the medical profession extends the hand of co-operation

'In order to avoid invidious contacts it should be made plain without delay that lay groups in any locality with which ethical physicians plan to co-operate will be submitted for the approval

(Continued on page 517—adv. rev.)

*Continued from page 516)*

f the county medical society, the decision of which society shall be arbitrary

"Lay organizations frequently misunderstand the position of organized medicine in the general health movement. There have been instances when the contact of the lay group has not been with the representatives of organized medicine, but in certain instances with individuals who did not represent the medical society. For mutual protection and achievement of the requisite end, this county decision would appear to be indicated. In case of doubt on the part of the local society, communication should be had immediately with the Education Committee of the State Society at 58 East Washington Street, Chicago, and the matter referred for prompt advice and counsel

### A HEALTH WEEK

A health week promoted by a county medical society is a unique event. The March issue of the *Atlantic Medical Journal*, the organ of the Medical societies of Pennsylvania and Delaware, contains the following editorial description of such a week in Lycoming County, Pennsylvania:

"The Lycoming County Medical Society, in conjunction with other agencies interested in public health, some time ago staged a health week which is something for other societies to 'shoot at'.

"Slips advertising health and periodic examinations were supplied to all the libraries to be given out with every book. Slips were distributed to druggists to be wrapped with every package. Health films were shown in every motion-picture house, and posters secured from the Pennsylvania Tuberculosis Society were on display in prominent places—industrial establishments, store windows, etc. Health talks were started before service clubs, social clubs, parent-teacher associations, and other organizations. These were to be continued throughout the winter.

"All these activities were preparatory to the meeting at which Dr. William P. Brown, medical secretary of the Pennsylvania Tuberculosis Society, spoke on the value of periodic health examinations and how they should be conducted. Dr. Brown spent a week in the county, and talked to the Rotary, Kiwanis, Lions, and various women's clubs.

"This is an inspiring program, and it is hoped that other county societies may take up similar activities."

## FLETCHERISM

Dr J H Kellogg of Battle Creek, Michigan has supplied the March number of the *Illinois Medical Journal* with an article on dietetic fads, Fletcherism, among them Horace Fletcher was a friend of Dr Kellogg and wrote popular articles on the importance of chewing every mouthful of food As he achieved popularity, he developed an ambition to achieve a place in the dictionary and succeeded with the help of Dr Kellogg, who wrote an article on Fletcherism which was widely copied Dr Kellogg says

"I soon found myself in trouble because of a new discovery made by Mr Fletcher and which he regarded as of such vital importance that he made it a leading feature of his philosophy Having observed that when he masticated thoroughly he ate much less than formerly and that in consequence he had small and infrequent stools, he concluded that daily bowel movements were quite unnecessary and, in fact, cultivated constipation by discarding all roughage from his diet, laying down as a rule that everything which could not be liquefied in the mouth should be rejected His theory was that by thorough mastication and avoiding all indigestible material, digestion and

absorption could be made so complete that there would be little or no residue left for evacuation

Mr Fletcher was not impressed by the fact to which I invited his attention that the colon is an excretory organ as well as a waste disposal mechanism, and that the liver pours into the intestine daily more than a pint of bile Mr Fletcher himself suffered greatly from chronic toxemia His tongue was heavily coated and his breath was highly malodorous His dentist informed me that his teeth were decaying more rapidly than in any case he had ever seen Prot William James who was at one time one of Mr Fletcher's most enthusiastic supporters, said to a friend, 'I tried Fletcherism for three months I had to give it up It nearly killed me' Dr Von Someren, Mr Fletcher's son-in-law and one of his most enthusiastic disciples, was under our care at Battle Creek for some weeks, for troubles resulting from colonic stasis, and later fell into a state of profound malnutrition and died Mr Fletcher himself died as a result of an exacerbation of a chronic bronchitis which was doubtless aggravated, if not chiefly caused by chronic toxemia"

## POSTGRADUATE STUDY

[The Journal of the Medical Society of New Jersey, for April discusses post-graduate study in the following editorial—EDITOR'S NOTE]

"Among the suggestions made to the Welfare Committee for establishment of post-graduate courses available to county society members was one which called upon the larger hospitals of the state to utilize their abundant clinical material for such teaching purposes. What has come to be known as the Kings County (N Y) Plan has been productive of excellent results in other places.

"We are delighted to note that one of our most progressive institutions has put this plan into effective operation and invites the physicians of that region to take advantage of its excellent facilities. The *Monthly Bulletin* of the Hackensack Hospital, March number, contains the following announcements:

*"X-Ray Friday Afternoons at Two o'clock*

"In order to make its facilities known and to assist physicians in the interpretation of radiographs, the X-ray Department will hold a clinical session every Friday afternoon from 2 to 3 o'clock. Dr R E Knapp will demonstrate X-ray plates in correlation with the pathology and then add short talks on the many conditions in which X-rays are of value in diagnosis and treatment. Special attention will be made of the newer advances in gastro-intestinal work, the use of tetra-iodide in gall-bladder diagnosis and oil emulsions to illuminate the bronchial tree.

*"Physiotherapy Friday Mornings at 10 o'clock*

"In response to many inquiries from physicians who are installing apparatus in their offices or who wish to learn the uses of physical agents, the hospital has arranged for a clinic every Friday morning from 10 to 11 o'clock in the Physiotherapy Department. This field of work is

new and growing steadily. The hospital has installed a department with equipment to cover every phase of the work. The number and variety of patients recommended for treatment now from 30-40 a day, offer such excellent material that the hospital feels it should be made available to any physician who is interested.

"Although the department welcomes the visits and inquiries of the physicians at any time, Dr S T Snedecor will conduct a clinic at this hour, with demonstrations of the apparatus, the technic of their applications, and short talks on the many kinds of disease in which physical treatment is of value.

"This is an excellent example for other hospitals to emulate. As previously announced, Dr O'Hanlon, Superintendent of the Jersey City Hospital, is arranging to start some similar series of lectures and clinical demonstrations at his institution. The staff of the Elizabeth General Hospital is now considering the proposition. At the City Hospital, Newark, Dr Harrison S Martland, has been for some time holding a "Medical Conference" each Monday evening at 10 o'clock using the autopsy material that comes under his official observation as City Physician. The many excellent hospitals in this state make it possible to have at least one central point of graduate study in every county, and every member of each county medical society should be cordially invited to attend and should exhibit an active participating interest in these periodic conferences.

"The plan is easy of execution. It calls for no special investment of funds. The teaching material is at hand in every hospital. The staff constitutes an existing faculty, and in assuming the role of "teacher"—the members are not presumptuous at all, not pretending to any special skill as educators but merely offering to share with their colleagues the opportunity to study medical problems of the day.

# Cod Liver Oil

for

## Every Baby

It is now quite the common practice among physicians to prescribe cod liver oil for all babies as a protective measure against rickets or mal-nutrition.

As it is advisable to start with a very small dose, it is important to know that the oil employed is of definitely known vitamin potency. Only a cod liver oil of guaranteed vitamin potency, which has been biologically tested can be depended upon to give the desired protection.

In the manufacture of PATCH'S FLAVORED COD LIVER OIL, every step of the process is carefully controlled, insuring an oil which is very potent and pleasant to the taste. Each lot of oil produced in our plants is biologically tested, for your protection.

If you can prescribe a small dose of pleasant tasting oil,—that's half the battle. Your patients, young and old, will appreciate such a product.

Let us send you a sample so that you may taste it and be convinced.

## HOW SANBORN METABOLISM APPARATUS WILL HELP YOU

You can accurately diagnose many ordinary perplexing cases with this apparatus. Helps to identify the important thyroid disorders, to study and treat more intelligently many SPECIAL CASES in diagnosis, therapy and surgery.

YOUR PATIENT WILL BE GRATIFIED BY THIS EXCEPTIONAL SERVICE. Metabolism Testing aids success, why rely upon outside tests? You or your assistant can test metabolism quickly, easily and accurately IN YOUR OWN OFFICE with the SANBORN GRAPHIC METABOLISM TESTER. Price, \$165.00. Sign coupon at bottom of their half page advertisement on Page xxiii and full information will be sent you complimentary.—Adv.

## THE TREATMENT OF FRACTURES

The ambulatory treatment of fractures of the lower extremities is a method of treatment that involves the use of the injured limb as a means of locomotion. This idea is not exactly new, since orthopedic surgeons as early as 1878 conceived the idea of allowing a patient with a fracture of the thigh or leg to walk about by means of apparatus designed to give support and corrective pressure to the injured member.

Dr. Scudder in his book, 'The Treatment of Fractures,' enumerated the advantages and disadvantages of the ambulatory method of treating fractures. Time is saved, the general health of the patient is conserved, the danger of hypostatic pneumonia is lessened, the primary swelling is often avoided, and is always less than by older methods, the secondary edema and muscular weakness are less, the functional usefulness of the whole leg is greater, there is less atrophy of the muscles of the thigh and leg, the amount of the callus is diminished, there is less stiffness of neighboring joints, and union occurs at an earlier date.

The only outstanding difficulty or disadvantage, that Scudder lists is the lack of perfect immobilization, and this has been secured since the time of his writing in the "Ambulatory Pneumatic Splint." This splint permits the comfortable use of extension, counter-extension and gives perfect immobilization, all combined with an unusual degree of comfort and convenience in bed cases.—Adv.

## NEW SURGICAL BELT

The new Surgical Belt, devised by the Wm. M. Eisen Co. and recommended by a great many of our leading surgeons has been proven a wonderful improvement over the old-fashioned Abdominal Supporter. The illustration (see advertisement on page xxv) shows the double lacing in the front which enables the patient to regulate the lifting support in any case of Ptosis, General Support or Ventral Hernia, and is recognized as a great improvement over the old style belt, the wide corset back which gives an excellent support, particularly in cases of Sacro Iliac troubles, and wherever a back support is required, has also been recognized as a great advantage. The new belt combines light weight with durability and ease of application and is as a Maternity Corset a most practical appliance, which gives definite support by lifting up the abdomen and relieving the strain from the back. No more cumbersome leg straps are required to prevent the appliance from slipping, as the new Surgical Corset is equipped with a full set of regular garters which keeps same in its proper place.—Adv.

## SOME UNUSUAL EFFECTS FROM THE USE OF CYCLOPLEGIC DRUGS\*

By E C ELLETT, M D, MEMPHIS, TENN, WITH DISCUSSION BY DR ALEXANDER DUANE

SHOULD there be any criticism of the title that has been used for this contribution, "Unusual Effects of Cycloplegics," on the ground that the effects noted in the first two cases are not unusual, a brief reference to the literature of the subject may not be out of place. In 1910, when Gifford reported a case of glaucoma brought on by the use of homatropine, only two other cases had been reported, and in 1916 when he presented the subject to the Section on Ophthalmology of the A M A he was able to collect only eight more cases from the literature, including four more of his own reported in that paper. But nearly every one who spoke in the discussion was able to add one or more cases, and it is probable that many more cases occur than those reported.

Case 1 Mrs H M aged 31, was seen in September 1906, complaining of headache and blurring of the vision on use. She was wearing glasses, +1.00 + 50 ax 180° in each eye. The only significant thing in her history was that her father was blind as the result of glaucoma. A cycloplegic was not employed, but her manifest hyperopia of +1.75 was corrected and she was relieved of her symptoms. The pupils, eye grounds, etc., were all normal. In November 1906 she was treated for conjunctivitis and soon recovered. In 1910 there was a return of the headache, and in my absence my assistant refracted her under homatropine. The error was +2.25 + 50 ax 90° in each eye. A change was made in the glasses and she was soon relieved. There were no unfavorable results from the use of the cycloplegic. In November 1916, being then 41 years of age, she was again troubled with her eyes, and in my absence from the city she again consulted the same physician whom she had seen in my office, who was now practicing independently. He again used homatropine presumably in the same strength (Gr 12 to the oz) and in the same manner (six drops at ten minute intervals) as before. The pupils remained dilated beyond the usual time, and three days after the drops were used the right eye became red and

painful. Eserine was used, 8 grains to the ounce, and depressed her so much that her physician was called to see her. Five days after the homatropine was used, that is November the 5th, 1916, I saw her and found the following:

O D Ball red, pupil 5 mm in diameter and a little irregular. Vn 20/100, +2.50 equals 20/20. Fundus normal. T (McLean) 35. O S Ball white, pupil 1.5 mm, Vn 20/60, +2.50 equals 20/20 m T (McLean) 50. Fundus normal.

She was treated with myotics and dionin which were interrupted about two weeks later on account of the appearance of signs of iritis in the right eye. The vision remained normal with glasses, the pupil of the right eye remained larger than the left, usually about 5 mm, and the iris atrophied in its upper part, the tension seemed normal to the fingers, and varied from 20 to 35 with the McLean tonometer. The fields, vision and eye grounds were normal. The patient was not regular in her visits, and myotics were used irregularly. I saw her last, or rather she saw me last, on September the 2nd, 1917, when the only thing abnormal was the slightly dilated right pupil. A year later she reported to my office while I was in the Army. The right eye showed all the signs of acute glaucoma, but the tension was not taken except with the fingers, and no record was made of the vision, nor any note of the condition of the left eye. Under the usual medical treatment she improved, and was told that unless the improvement was prompt and permanent an operation would be necessary. She left the city soon after this and went to Cleveland, Ohio, where she consulted an oculist who advised an operation. This she declined and I saw her again in June 1919. The right eye could see light. T 60 (McLean) pupil dilated and vertically oval due to the iris being atrophied above, media clear, disk deeply cupped. The left eye was blind and showed coarse injection, a widely dilated pupil and an opaque lens. Lauge operation on the right eye was without result, and she now has added to the loss of her sight, the tormenting symptoms which accompany the epithelial dystrophy so common in such eyes.

\*Read at the Annual Meeting of the Medical Society of the State of New York at New York March 31 1926

*Case 2* Mrs F C aged 28, was seen in March 1921 with the history that at the age of 14 she had sore eyes, with poor vision and photophobia, first in O D and later in O S. She recovered, but had a similar trouble at 18, and the vision of the right eye has never been so good since then. Vision was O D 20/40 O S 20/30 p. There was a slight veal ectropion at the margin of the pupil and both corneae showed fine deep vessels. At a later date with the slit lamp these were seen to be carrying blood. The former trouble was evidently an interstitial keratitis. The Wassermann was negative. Under homatropine the correction of a low compound M As gave 20/20 + and 20/20 p. The homatropine solution contained twelve grains to the ounce and was dropped in the eye every ten minutes for an hour. Nine days later word was received from her home in a near-by town that the left eye was red, blurred and painful, and that the trouble began with a pain in the eye three days after the drops were used. Letters and telephone messages secured her attendance at the office on April the 9th, nearly a month after the other test. The right eye was normal, vision 20/25 with glasses. The left eye saw 20/70 with glasses. Pupils 5 and 6 mm. Left not active to light. The eye grounds were normal. Tension was O D 48, O S 100 (McLean) tonometer. Under eserine the tension fell and vision rose in O S to 20/20. In ten days the tension was McLean R 28, L 24, Gradle R 24, L 11. Pupils 2 and 6 mm. Between this date and July the 18th the tension varied in the left eye from 42 to 90 McLean, and from 42 to 52 Gradle, the pupils about 4 mm and inactive. The fields showed O D slight contraction O S slight contraction and a variable relative scotoma in the lower temporal quadrant. This sometimes involved the blind spot, but neither on the ordinary perimeter or Peter's campimeter or the tangent screen could I ever demonstrate any constant enlargement of the blind spot. Dr W H Wilmer, who saw her in November 1921, thought her blind spot was almost double its normal size in each eye, but I could never make it so. Dr Wilmer advised operation if the symptoms persisted. On July the 18th, 1922, an iridotaxis was done on O S and on the 28th the tension was 35 McLean. September the 13th, T McLean 60, Gradle 52. The edge of the pupil was visible but the pupil was displaced up and out. The pupil reacted to slight and to eserine. March 1923, T Hg 24 McLean 40. Eserine was used in the left eye from the time of the operation until January, 1924, when it was stopped. Vision was normal. T Hg 24, pupil active in October 1925, the tension with Schiotz together with 26 and 23, Gradle 33 and 15, Hg 12 and 13. Eye grounds normal, vision 20/30 and 20/20 with glasses. Pupils active. Fields still showed a slight contraction in each eye.

Since 1916 a few additional cases have been reported.

W W Lewis<sup>1</sup> reports the case of a girl aged 22 who presented evidences of a former interstitial keratitis in the shape of obliterated vessel in the cornea. Homatropine, used for estimating the refraction, caused an attack of glaucoma. Only one drop of homatropine solution, 3%, was used. The eyes were inflamed, very hard, vision reduced to perception of light and corneae steamy. These symptoms disappeared in twelve hours under eserine, hot applications and sedatives. The subsequent history, after a few days was not known.

It is interesting to note that one of my cases had evidences of a former interstitial keratitis.

Lindner<sup>2</sup> reports attacks of glaucoma after the instillation of homatropine.

The first case presented by Dr Lindner concerned an old woman of 84 years, with thrombosis of a lateral branch. The glaucomatous attack occurred on the evening of the same day, although precautionary measures had been taken through twice repeated instillation of pilocarpin, and could be relieved only after energetic employment of myotics agents. In the other case, a man aged 44 years, homatropine was used, in the presence of a moderately deep anterior chamber, for the skiascopic determination of hypermetropic astigmatism. The glaucomatous attack produced thereby could not be relieved by means of pilocarpin but the increased pressure was relieved by puncture. "The relative rarity of such cases had probably led to a certain lack of caution in the employment of homatropine in recent years."

There are several points that appear from a perusal of the reported cases.

1 This form of glaucoma is more common in women. Of the eleven cases mentioned by Gifford in 1916, eight were women. Both of my patients were women.

2 The possibility of this unfavorable result is small. Millions of people have had homatropine put in their eyes and very few have ever developed glaucoma as a result of it.

3 Homatropine and other mydriatic drugs can not be said to cause glaucoma. They merely precipitate its development in eyes predisposed to its occurrence.

4 In the use of eserine and other myotics after the mydriatic has served the purpose for which it was instilled, we have an almost certain preventive of any trouble of this nature. Therefore the occasional occurrence of glaucoma is no more a reason for not using mydriatic drugs than is an occasional death from a general anesthetic a reason to withhold these blessings from those who need them. The dangers in each in-

<sup>1</sup> *Am Jour Oph* Vol 5 p 540 1922

<sup>2</sup> *Klinische Monatsblatt für Augenheilk* 1925 75 p 478

stance should be recognized and precautions taken to prevent their occurrence

5 In more than any other form of glaucoma, that which follows the use of mydriatic drug seems to be favorably influenced by myotic drugs and medical treatment

6 It should be the invariable rule to instill a myotic drug in the eye after the test is completed for which the mydriatic was employed

The other case is of quite a different character

Case 3 Mrs H aged 41, was seen in 1904 complaining of headaches, for which she had worn glasses for six years. From subsequent observation it was found that she was of a nervous temperament and easily disturbed, and in the twenty years that I have known her as a patient she has shown many and varied symptoms of functional disturbance. When first examined she had a baby less than a year old and since menstruation was re-established she had complained of ocular and occipital headache. The vision had always been poor in the left eye but she had never squinted. The eyes were normal inside and out. Vision O D 20/20, Manifest H +1.75. With +3.00 she read J<sub>1</sub> O S 18/200, not improved by glasses. Binocular vision and 4° exophoria. June 24th, 1904, homatropine and cocaine drops were instilled five times for refraction, the homatropine in the strength of twelve grains to the ounce. The test gave O D +2.25 equals 20/20 O S +5.50 +1.00 ax 90 equals 20/80. Three days later she accepted full correction and with +1.00 added she read J<sub>1</sub> and J<sub>10</sub>. August the 11th she complained that distant vision was blurred and it was necessary to reduce the glass 50 D to get 20/20. It was then noted that the right pupil was still dilated to the fullest extent, that is as widely as when the homatropine was first instilled. The eye was normal as to tension, field and vision. Eserine contracted the pupil, but one drop a day did not keep it down. Reducing the distant glass to +1.75 relieved the head and eye pains. In November, five months after the drops were put in, the right pupil was still 7 mm in diameter and inactive. The left 4 mm and active. There was a slight variation in the pupils. In December 1905, 4 and 3 mm and with +1.75 she read J<sub>1</sub> and 20/20. 1906, 4 and 3½, 1907, 5 and 3½, vision O D +1.00 equals 20/20, and J<sub>1</sub> with +2.00. 1909 pupils 3½ and 3, vision 20/20 and J<sub>1</sub> with +1.50. 1910 Same. 1919 4 and 3 mm, 1921 4½ and 3, distant vision same, +3.00 J<sub>1</sub>. No other symptoms appeared, tension, eye grounds and visual fields remaining normal, vision as recorded. In 1923 during my absence from the city, a colleague diagnosed glaucoma in the left eye, and performed an iridectomy. The diagnosis must have been based on the poor vision, which had always been present. Her hospital record was to the effect that the right pupil was normal, which it had not been for twenty years, and there was no

note of fundus changes or other symptoms upon which the recorded diagnosis of "secondary glaucoma" was made. Fortunately the poor eye was selected for this display of operative enthusiasm. In June 1924 the condition of the right eye was unchanged. February 1926, right pupil 4½ and inactive to light or accommodation. Left pupil, the round part is about 3½ and inactive, vision 20/20 and 20/60 with glasses. Reads J<sub>1</sub> O D with +2.50 added. Tension Sch 22 O U.

This case is unique in my experience and I have only found one case in the literature at all comparable to it. Decker<sup>a</sup> reports the case of a man, aged 36, who was refracted under homatropine. One drop of a 1.25% (6 grains to the ounce) solution of homatropine was put in the eyes every fifteen minutes for three doses. The refractive error was O D +1.50 +50 ax 90 O S +1.50 +1.00 ax 85. There were fine opacities on the posterior capsule of the right lens, the eye being otherwise normal. The pupils were normal in size after ten days and reacted to light but not to accommodation, but the accommodation was permanently suspended, or at least it was still absent fourteen months after the homatropine was used. A case of Dr Harold Gifford's reported to Dr Decker in a personal communication is mentioned in which the accommodation had not returned after two or three years.

In my patient presbyopia was already established and the muscle fibers of the iris were affected almost entirely, the ciliary muscle escaping. Though the drug was used in both eyes, only the right or better eye, was affected permanently.

In a few cases, four to be exact, marked constitutional symptoms have been observed in patients who had some mydriatic drug instilled into the eyes. In three of these patients the mental disturbance was most pronounced, and it is probable that an error occurred in using hyoscin instead of homatropine, due to a mistake in labels on the part of the manufacturer. The symptoms were not serious and soon passed away. These cases are mentioned because they are the only ones in my observation except those mentioned in this report, where unpleasant or unlooked for effects followed the use of mydriatic drugs.

#### DISCUSSION OF DR ELLETT'S PAPER BY ALEXANDER DUANE, M D, OF NEW YORK

Glaucoma following the instillation of Homatropine is certainly very rare. I use homatropine very frequently and, moreover, quite often in the sort of cases in which glaucoma is most likely to develop, i.e., subjects over 40. I think my records indicate that I have used homatropine more than 6,000 times, and I have had only one case of glaucoma attributable to its use. It is noteworthy that in this case, as in Dr Ellett's, homatropine had been used previ-

ously without ill effect. In addition, I have seen homatropine used in a great number of cases examined by others—in the clinics and in Dr Herman Knapp's office when I was acting as his assistant, and in none of these was glaucoma induced.

With regard to this accident my experience leads me to endorse completely all that Dr Ellett has said. It occurs so rarely that it furnishes no contraindication to the routine use of homatropine in refraction work. This is particularly so when we consider that as Dr Ellett rightly says, this accident occurs only in those predisposed to glaucoma, who, we may be sure, would have developed an attack anyhow, and it is in that case rather fortunate, at least for the patient, that the attack should develop under our eyes so that immediate steps can be taken to relieve it and to proceed at once to further thoroughgoing treatment of the eye condition, thus unexpectedly disclosed.

Of course, we should be on our guard and try to avoid the production of glaucoma by a cycloplegic. Before instilling homatropine in persons of forty or over, I regularly take the finger tension, and in cases of doubt the tension with the tonometer. In fact, I may say I have got into the habit of taking the finger tension as a routine measure in all cases of presbyopic age that come to me for examination of the refraction whether I am going to use a cycloplegic or not. I think it also a good plan in the older subjects after the examination under a cycloplegic is over to take the finger tension again and to instill eserine.

One other rather more frequent inconvenience that occurs after the use of homatropine is an unduly prolonged effect on the accommodation. In this regard I have made studies in several thousand cases of homatropine cycloplegia. In all of these cases, careful measurements of the accommodation were made before the homatropine was instilled, and in a very large number further measurements were made a week or so later. My results may be thus stated:

1 An effect on the accommodation obvious to the patient, *i. e.*, interfering with his ability to read, lasts usually for about 48 hours. In some, especially in the young, the ability to read may be regained in 24 hours or even much less. This is no indication that the accommodation is not considerably affected, and hence reading sooner than 48 hours should be discouraged. As opposed to these cases there are not a few cases in which the evident disability of the accommodation lasts for from 48 to 60 hours.

2 The dilatation of the pupil usually persists for about the same period, *i. e.*, 48 hours and

sometimes longer. It may be evident when there is no disability for reading.

3 In some cases the disabling effect on the accommodation and pupils is prolonged for several days (3 to 6). I have records of eleven such cases. They ranged in age from 15 to 50 (five being under and five over 32), and for the most part showed a slight hyperopia and astigmatism. In several the cycloplegia was marked and, although eserine was repeatedly instilled, this had no permanent effect. It is to be noted that all but three of these cases occurred in the days before I made up my own homatropine solution, as I have done invariably now for 18 years, and I suspect strongly that in some of these cases there had been substitution of atropine. This seemed particularly likely in three cases which all occurred about the same time and in all of which, the same solution was used.

4 Apart from these cases, which certainly are quite rare my observations show that quite generally during a period of some weeks after the instillation the accommodation when measured by careful tests is less than when tested before the drops were used. This causes the patient no inconvenience as a rule, but it has a very direct bearing on the prescription of glasses. One conclusion, important in practice, which I have drawn from my measurements is that it is unwise to attempt to prescribe a glass from a post-cycloplegic examination made within a week of the time the homatropine was instilled. If the examination is made sooner the residual deficiency of accommodation may be such that, particularly in presbyopic cases, we are led to prescribe a glass that is too strong for near work.

Whether this prolonged moderate deficiency of accommodation found after the use of homatropine represents a real reduction produced by a lingering effect of the drug or rather represents simply a relaxation due to the let-up allowed by the use of a correcting glass, I do not know although the latter explanation seems to me more probable.

In some patients—but fortunately very few—we find an actual idiosyncrasy against homatropine, which nauseates them or makes them feel faint or otherwise uncomfortable. In such cases another cycloplegic may be tried, but in general I have thought best to depend upon results made without cycloplegia.

In a few cases, on the other hand, homatropine renders the patient more comfortable, affording a sense of rest and relief. One patient of mine, a physician, told me that for quite a period in her life her eyes were never comfortable except when under homatropine.

## THE NECESSITY FOR BLOOD SUGAR ESTIMATION IN SUSPECTED DIABETES WITH OR WITHOUT GLYCOSURIA

By HORACE GREELEY, M D, BROOKLYN, N Y

IT was formerly believed that all cases in which the carbohydrate metabolism was faulty could be detected by the symptoms and examination of the urine. That this was a mistake has been shown, during the last few years, in numerous contributions to medical literature reporting cases with diabetic symptoms without glycosuria, but with abnormally high blood dextrose. As additional evidence on this subject, and for other points of interest, in this article are presented the findings in a hundred cases in which blood and simultaneous urine analyses were made during the past year. All the patients were from the private practice of Brooklyn physicians, referred for the examinations in question.

Specimens of blood and urine were taken at the same time, and the patients were uniformly on an empty stomach. Folin's method of blood sugar estimation was employed in all instances. Copper test of the urine (Fehling's), confirmed always by fermentation, was the basis of all urinary findings.

None of the cases reported in this article were receiving insulin at the time of examination, so that the high blood sugar findings, at the time the urine was sugar free, could not have depended upon insulin-altered dextrose, as was suggested as a possible explanation of high blood sugar findings without glycosuria, in a series of diabetics reported by Major and Davis (J A M A, Vol 84, No 24, p 1798, June 13, 1925).

Classifying the 100 cases according to the amount of blood sugar present, we find, from the table, that among the cases with primary disturbance of the carbohydrate metabolism that (a) 19 showed blood sugar of 120—150 mgs, but only two of these had a simultaneous glycosuria (1%), none showed signs of renal irritation, (b) that 51 had over 150 mgs of blood sugar, and that, of these, 44 had neither albumin nor renal elements (casts, etc) in the urine, but 30 of the 44 showed glycosuria of from 1—5%. Renal irritation was manifested in the remaining 7 of the 51 cases, which 7 also showed glycosuria (1—3%). Cases in which the carbohydrate abnormality could be regarded as secondary comprised (c) 27 of nephritis, including 4 with blood sugar under 120 mgs (one showing simultaneous glycosuria of 13%), 16 with blood sugar of 120

—150 mgs (one with glycosuria of 1%), and 7 with 150—250 mgs (one with glycosuria 01%), (d) the three remaining cases of the series were one of acute nephritis (case 50) which had a blood sugar of 167 mgs, one of renal glycosuria, with 105 mgs in the blood and 2% in the urine, and one four-plus Wassermann case.

Of the total 100 cases, 24 had been diagnosed previously as diabetic, and 76 were "new cases" in which the examinations were made to confirm clinical suspicions or as "feelers" in obscure debility cases.

All the 24 known diabetics, except one, besides an abnormally high blood sugar showed sugar in the urine—this indicating how largely the recognition, in everyday practice, of a diabetic depends upon the presence of glycosuria.

Of the 76 "new cases," 47 can be classed as uncomplicated disturbances of the carbohydrate metabolism. Omitting one of these (the case of renal glycosuria) we find, of the remaining 46 cases which showed diabetic blood sugar findings, only 15 showed glycosuria simultaneously with hyperglycaemia. Consequently, the diagnosis would have been missed in 2/3 of the cases, if the blood sugar estimation had not been made.

To show the definiteness of the diabetic conditions that would have failed of recognition without blood sugar estimation, attention is called to the fact that, of the 31 "new cases" without sugar in the urine, 16 had 120—150 mgs of dextrose per 100 c c of blood, 8 had 150—200 mgs of dextrose, 6 had 200—300 mgs, and 1, 400 mgs.

The normal range of blood sugar is usually put at between 80 and 120 milligrams, in 100 c c of blood, and the kidney threshold has been stated to be at about 150 milligrams. It is apparent that such a normal range is dependent upon several factors: (1) the amount of carbohydrate taken in the food, (2) the rate of its absorption, (3) the rate of sugar storage, (4) the operation of the body's mechanism for freeing and utilizing the stored sugar, (5) and lastly the sensitiveness of the kidneys to blood sugar, and their excretory power over it when it reaches a certain amount.

(1) With the average amount of carbohydrate, the average normal person certainly shows no variations in blood sugar inconsistent with the above mentioned normal range, and it may be said that such a person's blood sugar (with the usual diet) varies but little at any time of the twenty-four hours, owing to either the stage of digestion or the amount of body activity, (2) the rate of absorption of carbohydrate probably never exceeds the rate of storage in a normal person, when the absorption waits on hydrolysis, as of starchy food, but when a sugar, such as

NOTE. Distinct results with either Fehling's Benedict's or other qualitative copper tests for sugar in the urine are only obtained when 0.25% or more of dextrose is present since the amount of reaction given by lesser amounts of dextrose may be simulated by various other substances present in the urine. The procedure adopted was to ferment with yeast all urines with which the copper test gave a positive or a suspicious reaction. By this method urines containing 0.1% or more of sugar give definite amounts of carbon dioxide, and even half the percentage stated is clearly shown. The fermentation tubes used were especially graduated through fermentation in them for a given time in an incubator of various definite percentages of dextrose added to normal urine. All yeast used was tested for unfermented carbohydrate in a control.

Med 37 88, Jan 26) The condition is accordingly, probably, due to unusual sensitiveness of the renal epithelium to dextrose

That this sensitiveness varies is shown in the cases of nephritis, some of which show abnormally high blood sugar, and others a slight glycosuria, when true diabetes can be excluded, by either dextrose tolerance tests or by symptoms

Of the cases of chronic nephritis mentioned, it should be noticed that 33, 41, and 95 show both hyperglycaemia and glycosuria Case 95 was suffering from uraemia at the time of examination and died within 24 hours A case of acute nephritis (No 50) showed 167 mgs of blood sugar

According to Linder, Hiller and Van Slyke (J Clin Invest 1 217, Feb, '25), in severe glomerulo-nephritis, hyperglycaemia and glycosuria are present, and the threshold is apparently lowered In sclerotic kidney, the blood sugar is higher than usual and the threshold is raised As they found that the combustion of sugar was as efficient in all types of nephritis as in normal persons, they concluded that hyperglycaemia in such cases was due to some obscure factor

It seems certain, however, that renal disease can directly cause both hyperglycaemia and glycosuria, since injections of sodium tartrate cause nephritis in rabbits, which is accompanied, irregularly, by either of these manifestations (Underhill and Wilens, J Biol Chem, Vol LVIII, 1, Nov, 1923) "Phlorhizin diabetes" has also been proved to be due to kidney injury (Nash, J Biol Chem, LI, 1, Mar, 1922) In this connection one is tempted to suggest the following explanation of the hyperglycaemias of renal disease This is that, since the nephritis eventually causes retention of wastes, and these accumulated wastes (nitrogenous or other) act directly or indirectly to increase the blood pres-

sure, a process with which the suprarenals are concerned, there is an over-stimulation of suprarenal activity Since suprarenal secretion stimulates the output of liver sugar, there is a consequent increase of blood sugar beyond that required under normal conditions The cause of the glycosuria is plainly the damaged epithelium

### CONCLUSIONS

The absence of sugar from the urine does not show that a patient is not diabetic, in more than one-third of the average run of cases

The presence of sugar in the urine does not prove a case diabetic, since we might be dealing with nephritis or even renal glycosuria

The presence of evidence of nephritis, both clinical and urinary, together with glycosuria, might be due to either primary nephritis with a glycosuria due to renal deficiency, or yet to a nephritis caused by a pre-existing diabetes

Estimation of blood sugar is the only way in which one may intelligently decide the question as to whether a patient is diabetic and, if so, gain an idea of the extent of his pancreatic deficiency

The absence of sugar from the urine of a proved diabetic, unless the particular diabetic be proved to have a normal threshold, cannot be taken to indicate that treatment has restored the balance of carbohydrate metabolism

The blood sugar must rise above the normal threshold before evidence of renal irritation or secondary nephritis can be produced

In nephritis, owing to the damaged renal epithelium, we may find glycosuria with a normal blood sugar or, that which is more common, both glycosuria and hyperglycaemia—the latter probably due to excessive mobilization of glycogen by suprarenal over-secretion, excited by retained wastes

## THE SPECIFIC EFFECTS OF DIATHERMIA\*

By GUSTAV BUCKY, M D, NEW YORK, N Y

VERY frequently a physician says to his patients, "I am now going to use heat in the treatment of your case" In the term heat he includes such forms of it as radiant heat, conductive heat, and diathermia From this it follows that he places diathermic treatment in the same category with other types of heat treatment, and that he expects to get the same effects and results from each of them

The specific actions of diathermia being apparent, the conditions in which it is indicated will become evident and it will be understood why more marked results are obtained with this treatment than commonly follows other methods of heat application

An electric current is sent through the body in diathermia as in faradic or galvanic treat-

ments In diathermia, an alternating current of moderate tension is employed differing from a faradic current in the number of alternations These alternations in diathermia are between one and two million per second,  $\pm e$ , the direction of the current is reversed about one million times in that period The current goes back and forth in the wires or in the body something as does the shuttle of a loom One naturally thinks that a current of this sort would cause such irritation as to be unbearable, but actually this is not the case Such a tremendous current, which would cause death if it were of any other type, is followed by no pain or irritation and causes practically no discomfort The explanation is as

\*Read before the Harlem Medical Society New York, November 1923

follows. The atomic elements of the cells are not disturbed by the transmission of such a high frequency current, and there is no electrolysis. In other words there is no cellular change. Nernst has shown that electrical irritation depends on the electro-chemical changes in the body. Since there is no electro-chemical dissociation with diathermia, there can be no irritation, and because of its absence, there is also no stimulation of the nerves with resulting sensations. Thus we can increase the intensity of the current beyond even 3 amperes, whereas with other types of current we are able to apply only a few milliamperes. Because we are able to increase the intensity of the current we can create warmth, a phenomenon not noticed with a current of low intensity. From this it is clear that the patient will experience no other effect than that of warmth.

Where, then, is the heat generated? The answer to this is very simple. Wherever the current flows a part of it is converted into heat, and since the current flows through the entire body, warmth is experienced everywhere, even in the deep tissues.

This is one of the main differences between diathermia and the other forms of heat application. Iselin has shown that the temperature of the skin is never higher than 37° centigrade when the body is subjected to a hot air bath of 120° centigrade. That means that energy in the form of heat cannot penetrate the skin. If we notice any rise in body temperature after a steam bath for example, we explain it on the ground that the moist air prevents or decreases the escape of heat generated by the body itself. Increased temperature during one diathermic treatment is due to the conversion of the electric current into heat in the body, whereas increased temperature in the other forms of heat treatment is due to a storage of heat produced by the body. In the diathermic treatment, physical energy, which is converted into heat is transmitted to the body instead of conserving the heat produced by the body itself as in the other methods. Therefore, the blood instead of rushing to the surface to give off its excess heat, flows to the tissues which are warmed by the electric current in order to equalize the temperature throughout the body. From this it will be properly concluded that diathermia creates an afferent hyperæmia in the deep tissues, while the other heat applications produce a superficial efferent hyperæmia. As proof that all this is not mere theory, the parts of the body treated with radiant heat, for example, are colored deep red, whereas in diathermia the skin is normal, even the area directly in contact with the electrodes.

This also demonstrates that the effects of these two fundamentally different hyperæmias

must also be widely dissimilar. From this, important conclusions the indication of proper treatment can be made depending on whether we desire an increased or a decreased flow of blood to or from a particular organ.

Since hyperæmia and secretion are interdependent it is easy to understand, that the secretion of deep seated organs with diathermia alone can be influenced. In practice this is actually the case, and an increased secretion follows a diathermia treatment. Metabolism is also increased. Knowing this, results can be regulated by employing the proper technique—an impossible consummation with the other methods of heat application.

Hyperæmia, secretion and metabolism are the deciding factors in cellular activity. No wonder, therefore that so many symptoms of disease can be dissipated by our ability to control these factors. Among these are included the relief of pain, a general sedative action and the excitation of resorption, exudation and transudation—in other words, the return to normal.

The effect on bacteria can also be explained to a large extent by the increased heat on the thermolabile bacteria. This makes it necessary to differentiate between the direct and indirect effects of diathermia on bacteria.

The energy saving effect of diathermia, as first shown by Bergonie, is of great importance. The passing of the electric current through the deep tissues is quite comparable to the addition of free energy, and can be utilized as readily as food. Furthermore, reserve materials such as fat are saved for possible future emergencies. The body derives energy from the heat producing effect of diathermia without itself doing any work just as if it were absorbing assimilated nourishment without preliminary digestion.

The practical value of all this is that diathermia does not increase the labors of the body as does the steam bath. The increased sweating and the marked changes in the circulation during a steam bath involve considerable work on the part of the body. As proof that this taxes the strength of the body, fatalities frequently occur after a steam bath as the result of cardiac insufficiency. On the other hand, patients with very weak hearts or myocarditis can stand diathermic treatment without any ill effects. This proves that neither the body nor the heart is called upon to do more work even after a general diathermic treatment, where the electric current passes through the whole body and causes a considerable rise in temperature. Diathermia should therefore displace the steam bath in the treatment of cases complicated by heart disease.

The numerous specific effects of diathermia

readily explain the wide range of its indications and uses. At first glance these would appear more or less like the exaggerations of a quack to the uninitiated. But we are still putting too much faith in the theories and experiences gathered during the years of drug treatments. The experiences of drug therapy are unconsciously being transferred to the field of physical methods. However, we are still governed by the age-old medication point of view whereas the knowledge of the physical means and of our ability to use them is practically recent, dating only from the end of the last century. We are accustomed to find certain definite results following the administration of particular drugs. (A drug for raising the blood pressure always does so, and does not lower it, a stimulant will not work as a sedative, etc.) But with physical methods we do not obtain the same results in every case, and we are at a loss to explain these inconsistent results. For example, we find that in diathermia we sometimes get an increase and sometimes a decrease in secretion, probably through the regulation of the circulation. High blood pressure is sometimes lowered and low blood pressure is sometimes raised. In general we find a tendency to return to normal following a treatment. The mechanism of these results present very interesting problems, but for the time being we must be content with the experiences of clinical applications, although the theory is being studied more and more from day to day.

It is needless for one to enumerate the indications for diathermia, as the knowledge of the specific actions of diathermia will better enable one to judge the indications. Let it be borne in mind that diathermia has a regulating effect on the circulation. The treatment of inflammations, especially when deep-seated, comes in this category. In certain acute stages of inflammation such as tuberculosis, articular rheumatism and appendicitis, diathermia is contraindicated. In others, however, as for example the acute stage of tendovaginitis, furunculosis, otitis media, etc., the results are sometimes amazing. Generally however, we must be careful in such acute inflammations, accompanied as they are by marked tissue involvement and a high degree of hyperæmia.

Chronic inflammations of any organ with practically no exception are the most fertile field for diathermia.

Other conditions such as frost-bite and arterio-sclerosis, which are also due to circulatory disturbances, and certain nervous conditions such as Raynaud's disease, fall into this class, and their treatment with diathermia often yields the most astonishing results. The treatment of pneumonia might even be placed in this group.

The relief of pain is marked in inflammations and especially so in neuritis. The effects of diathermia on lumbago, rheumatism, pain following local anaesthesia, periodontal inflammation, traumatism, etc., are pronouncedly favorable. Its resorptive or absorptive effect can be noted in all effusions, as in hematoma, after-treatment of fractures and thrombosis. In mental excitation and in mental diseases diathermia exerts a sedative action. In the treatment of melancholia, for example, quite remarkable results have been obtained, thereby obviating the necessity for sedative or narcotic medication.

Secretory regulation may be observed following the employment of diathermia in nephritis, in hepatitis, in gastric neurosis, etc. Interesting results were obtained from the uses of diathermia in treating the breast of a nursing mother with an insufficient milk supply, the production of milk being markedly increased.

Its beneficial effects, probably secondary on the hostile bacteria present, have frequently been observed in the treatment of infectious arthritis, gonorrheal prostatitis and epididymitis. Its aid as a conservator of energy is apparent from the rapid recovery and the improved general condition following diathermic treatment during convalescence, especially after infectious disease.

That diathermia has a beneficial effect on metabolism is shown by the cessation of all the symptoms of nausea from anaesthesia following its uses. A marked increase in appetite and a marked improvement of the Roentgen-diseases if treated after each X-ray treatment, is noted after a diathermia treatment.

The more salient features of diathermic treatment have been merely touched upon.

## CLINICAL APPLICATIONS OF THE FUNCTIONAL HEARING TESTS\*

By C STEWART NASH, M D, ROCHESTER, N Y

The clinical applications of the functional hearing tests are precisely what each individual aurist makes them. If I were to classify otologists according to their attitude toward this particular phase of the work, each one of us would fall into one of three distinct groups. We should belong either to (a) the academic group, or (b) the non-academic group, or (c) a combination form of the first two.

The *academic group* includes these individuals who have the equipment, the knowledge, the time, and the desire to do good work. They are best exemplified by the full-time teacher of the medical college, the man associated with certain clinics, the man of independent income who can afford to limit his practice to just the number of patients that he can examine and treat in an ideal and "academic" way, and the young otologist whose clientele is not yet established and who has leisure thrust upon him. These men are actually giving to their patients what all our patients believe that we are giving them.

The *non-academic group* includes those men who have the equipment, who may or may not have the knowledge, but probably do not, who may or may not have the time, and who have no special desire to do good work in this or any other field of otology. Unfortunately, rather a large percentage of otologists can be found in this group. Many of these men are so busy that they have time only to treat the deafness and no time to make a diagnosis.

The *combination form* is composed of otologists who have the equipment, the knowledge, and the desire to make good functional hearing tests, but who are seriously cramped for time. They want to do good work, but their practice has increased beyond the point at which the individual patient can receive in full measure all that the aurist has to give. This doctor has an office full of patients, among whom are to be found prospective tonsillectomies, submucous resections, mastoidectomies, and so forth, and tucked back in the corner is a man whose deafness has been increasing for some time and who consequently has come to this particular otologist on the recommendation of his family physician who lives in another town many miles away.

When the patient arrives in the treatment room and states his complaint to the doctor, the procedure is as follows. His ears, nose and throat are examined by inspection, his eustachian tubes are inflated, and since his drums are slightly retracted, and there is no history of deafness in the family, he is told that for him to have his best hearing the tubes must be kept open and that a series of treatments are necessary to ac-

complish this end. The doctor makes a mental note to check this case with functional hearing tests as soon as he gets time. The patient takes the treatments and when the tubes are open the hearing improves and the doctor gets the credit for being a good "ear man." On another occasion, when there are fewer in the office, another patient comes in complaining of deafness. The examination is conducted as before, but since the physician is not so pressed for time a fuller effort is made to determine the cause and the extent of the disability. In addition, then, he tests with a whisper and spoken voice at a distance of four or five feet, multiplies a numerator and denominator by a convenient factor, and expresses the patient's disability in terms of 20/20. He also tests the bone conduction and, compares it with the air conduction, and the examination is complete. His conscience pricked him in the first case and in the second he salved it by these two maneuvers. As I have said before, this man knows how to do academic and scientific work and he wishes to do it, but he is seriously pressed for time.

So far I have made a hard and fast classification of all otologists according to their attitude toward the clinical applications of the functional hearing tests. You may quite justly ask me how I arrived at these conclusions and by what right these assertions are made. In the past four years it has been my opportunity to examine in an academic way some two thousand to twenty-two hundred cases of deafness or questionable deafness outside of my own private practice. Many were government compensation cases, upon which percentages of disability had to be made and from which malingerers had to be excluded, others included medico-legal and other forms of adjustment cases. On all of these, my work was either actually checked, liable to be checked, or else I was checking some one else's work. This experience, you see, gave me a special opportunity to determine what other men were doing in this work and also perhaps made me a little keener myself.

It might be interesting to state that all of this work was done before the audiometer became part of the office routine. The tests consisted of a determination of the ability to hear whispered and spoken voice at no less than twenty feet. The Schwabach, the Rinne, the Weber, and the range of hearing were tested at 64, 128, 256, 2,048, and somewhere around eight to ten thousand D B per second with the Galton whistle. The percentages of disability were arrived at, by what we call a utility method which you can see might be somewhat elastic so far as the judgment of one's peers is concerned.

\* Read at the Annual Meeting of the Medical Society of the State of New York at New York March 30 1926.

In all of this experience I have never yet been confronted by an otologist of the academic type. Whether the medico-legal, compensation, and industrial world shun our more academic brothers is a question I have not yet answered.

The non-academic type in this field of endeavor, however, are plentiful, and when confronted by a condition in which they are obviously in the wrong, one of two reactions has always manifested itself. First, they may laugh it off as a good joke and say, "We really didn't examine the patient very well." Or else they become abusive and swear before a jury or commission that what we consider as an axiomatic truth, in this particular case is probably untrue. I was called in to see a case, the facts of which are briefly this. A woman aged 65 took down the telephone receiver and was met by a terrific buzz in her ear. She immediately became nauseated, dizzy, faint, and deaf. After two days the condition had not subsided, and her general doctor notified the telephone company, who dispatched an aurist to investigate the matter. He inspected her ears, nose and throat, noted a slight retraction of both drums and reported to the company that she had a chronic catarrhal deafness, implying thereby of course that the blast in the ear had nothing to do with the deafness. On my examination she withstood all kinds of malingering tests and was very consistent in demonstrating that the nerve function in the affected ear was definitely impaired. On successive examinations the nerve function gradually came back until what was probably her normal hearing was restored. This took place before any settlement or adjustment was made with the company. The company otologist is a friend of mine, he laughed and said that he had not made any functional tests in her case. The company paid the bills. Another case was that of a woman aged 40 who had been complaining of deafness over a period of about a year. At weekly and monthly intervals she had had her eustachian tubes inflated, but her deafness was unimproved. It became my duty to examine this patient. On examination, both canals were found to be filled with impacted wax which had *not* collected there within a few weeks. On removal of the wax the hearing was decidedly improved, and after adequate time for the canal and drum to resume their normal character she heard so well that she considered further treatment unnecessary. The doctor insisted that her increased bone conduction proved middle-ear involvement.

The third classification or combination form of individual does not like to become entangled

in any case where his functional-hearing-test work is likely to be checked. He does not represent the innocence of the first form of the non-academic, nor the narrow stubbornness of the second. He is wary and does his work well enough not to make gross errors, but nevertheless he does to a certain extent fail to give his patients what they really pay for and what they may expect from a man of his reputation and ability. A young lady went from the city of Rochester to an otologist of high rank in his profession and particularly popular with the laity. He examined this woman by inspection, inflated her eustachian tubes, inserted some of his "magic fluid," charged her a respectable fee and advised her to return for further treatment. On the second treatment he did functional hearing tests and assured the patient that her hearing was greatly improved. She thanked him very much and said that she did not know how he could tell anything about it since he had never tested her before. Now he did better than many of us do, because he did examine her on the second visit, but just the same he had not treated that patient in a measure consistent with his ability and reputation, and consequently to just that extent had in reality defrauded her.

From what has been said so far, you are beginning to think this whole matter of functional tests is either unsatisfactory or impracticable. As a matter of fact this is probably true. If you do functional hearing tests on a patient, and that particular work is to be checked, and you know it, you will probably do academic work, but if an unsuspecting patient has absolute confidence in you, and you are busy, you will probably treat him and put off the scientific examination from one time to another indefinitely.

At present I am doing functional hearing tests on every case of deafness that I examine or treat, and am repeating these tests at intervals regardless of the fact that the element of time is most distressing. To do otherwise is unfair to the patient and incidentally jeopardizes the security of my own judgment.

Briefly and in conclusion, the functional hearing tests are used in my office for the following reasons:

- 1 To differentiate and classify deafness
- 2 To record the condition of an individual case throughout duration of deafness
- 3 To determine percentages of disability
- 4 To adjust medico-legal and compensation cases
- 5 To assist in the localization of intra-cranial lesions

## SOME MISCONCEPTIONS IN THE DIAGNOSIS OF MOTOR ANOMALIES\*

By ALEXANDER DUANE, M.D., NEW YORK, N. Y.

**I**N any branch of diagnosis it is important that we should start with a clear conception of the nature of the conditions that we are investigating. Otherwise the significance of the tests that we supply for the detection of the conditions escapes us.

This statement is particularly true with regard to motor anomalies of the eye. Here, I believe, two fundamental misconceptions have prevailed among many, and have militated against accurate diagnosis and effective treatment.

The first error consists in regarding a motor anomaly simply as a departure from orthophoria without inquiring into the conditions that produce this departure. In other words, many observers simply record the fact that the patient shows this or that amount of esophoria, exophoria, or hyperphoria in distant vision, without determining how these relations change at near points and how they change in different directions of the gaze, and also without determining the ability of the eyes to perform parallel movements in the six principal directions, or to converge or diverge. The importance of determining all these points if we wish to arrive at anything like a correct diagnosis has been repeatedly signalized. I myself have for thirty years been urging the fundamental importance of regarding and handling motor anomalies in this way. Yet repeatedly I receive letters asking for a diagnosis and suggestions for treatment when the only data given are measurements, made repeatedly and with great care, of some exophoria or hyperphoria present. Such data, however accurate, are altogether insufficient for a proper understanding of the nature of the case or for the application of suitable treatment. This should be obvious when we consider that the eyes are in constant action, performing all sorts of combinations of conjugate, convergent, and divergent movements, that, in general, some interference with these movements is the thing that causes the motor anomaly and the patient's symptoms, and that the deviation that we find in the primary position is but one result, and that perhaps the least important, of the condition we are seeking to correct. The deviation found is but a symptom, and to treat it as a substantive affection without determining the conditions that underlie it would seem as strange a thing as for a physician these days to treat a case of dropsy simply as dropsy without seeking for its cause.

In many of these reported cases it is not even stated whether the deviation found is regularly or sometimes a squint or whether it is at all times a heterophoria. Yet this distinction is important—more important, indeed, than the actual measure of the deviation itself—since it shows how

readily the eyes can be made to submit to fusion control. On this very point often hinges the question of treatment and especially of operation.

The second error seems to me to lie in the conceptions that some hold regarding the essential nature of orthophoria, heterophoria, and squint. To understand this let us consider what these conditions show as to the actual state of the eyes.

The great majority of persons when viewing an object with both eyes exhibit what we call binocular fixation and binocular single vision, i.e., both eyes are directed sharply at the object and both simultaneously see it. In a few cases when their attention is directed at an object, and they are looking at it with both eyes, one eye obviously deviates. We thus divide mankind into two classes, squinters and non-squinters, the former being evidently abnormal. But some of the non-squinters prove on examination to be abnormal too, for whenever we interpose a sufficient obstacle to clear binocular vision, we find that one eye deviates, to return to the fixing position when the obstacle is removed. These cases we group under the head of heterophoria. Furthermore, if we examine these cases in different ways and at different times, we find that the amount and persistency of the deviation vary with the means employed to elicit it and with the time during which the conditions of normal binocular vision are suspended. We find, in fact, that, according as we change the conditions of the examination, a deviation may be made to vibrate between an orthophoria and a heterophoria of varying amount or between a heterophoria and a squint.

It is often argued that a person who exhibits such variations has a muscular error equal to at least the largest amount that he admits by the tests and that when he shows less he is concealing part of the error by effort. He is thus compared to a hyperope who at times reveals part, at other times none of his refractive error, and who reveals all of it only when put under atropine. From this viewpoint true orthophoria would correspond to emetropia, heterophoria to a latent hyperopia, and a squint to an absolute hyperopia.

This analogy, with its implications as regards the significance of the tests, is based, it seems to me, on a fundamental misconception. The hyperopia in the one case represents an absolute static condition, i.e., the refractive state which appertains to the eye when making no accommodative effort whatever and which is conditioned solely on the shape and constitution of the refractive surfaces. This state is thus a perfectly determinate and stable affair. It is proper then to say that the accommodative effort masks or conceals the true refractive condition. But the muscular state of the eye (orthophoria or heterophoria) is quite a different thing. When without

\* Read at the Annual Meeting of the Medical Society of the State of New York at New York, March 30, 1926.

In all of this experience I have never yet been confronted by an otologist of the academic type. Whether the medico-legal, compensation, and industrial world shun our more academic brothers is a question I have not yet answered.

The non-academic type in this field of endeavor, however, are plentiful, and when confronted by a condition in which they are obviously in the wrong, one of two reactions has always manifested itself. First, they may laugh it off as a good joke and say, "We really didn't examine the patient very well." Or else they become abusive and swear before a jury or commission that what we consider as an axiomatic truth, in this particular case is probably untrue. I was called in to see a case, the facts of which are briefly this: A woman aged 65 took down the telephone receiver and was met by a terrific buzz in her ear. She immediately became nauseated, dizzy, faint, and deaf. After two days the condition had not subsided, and her general doctor notified the telephone company, who dispatched an aurist to investigate the matter. He inspected her ears, nose and throat, noted a slight retraction of both drums and reported to the company that she had a chronic catarrhal deafness, implying thereby of course that the blast in the ear had nothing to do with the deafness. On my examination she withstood all kinds of malingering tests and was very consistent in demonstrating that the nerve function in the affected ear was definitely impaired. On successive examinations the nerve function gradually came back until what was probably her normal hearing was restored. This took place before any settlement or adjustment was made with the company. The company otologist is a friend of mine, he laughed and said that he had not made any functional tests in her case. The company paid the bills. Another case was that of a woman aged 40 who had been complaining of deafness over a period of about a year. At weekly and monthly intervals she had had her eustachian tubes inflated, but her deafness was unimproved. It became my duty to examine this patient. On examination, both canals were found to be filled with impacted wax which had *not* collected there within a few weeks. On removal of the wax the hearing was decidedly improved, and after adequate time for the canal and drum to resume their normal character she heard so well that she considered further treatment unnecessary. The doctor insisted that her increased bone conduction proved middle-ear involvement.

The third classification or combination form of individual does not like to become entangled

in any case where his functional-hearing-test work is likely to be checked. He does not represent the innocence of the first form of the non-academic, nor the narrow stubbornness of the second. He is wary and does his work well enough not to make gross errors, but nevertheless he does to a certain extent fail to give his patients what they really pay for and what they may expect from a man of his reputation and ability. A young lady went from the city of Rochester to an otologist of high rank in his profession and particularly popular with the laity. He examined this woman by inspection, inflated her eustachian tubes, inserted some of his "magic fluid," charged her a respectable fee and advised her to return for further treatment. On the second treatment he did functional hearing tests and assured the patient that her hearing was greatly improved. She thanked him very much and said that she did not know how he could tell anything about it since he had never tested her before. Now he did better than many of us do, because he did examine her on the second visit, but just the same he had not treated that patient in a measure consistent with his ability and reputation, and consequently to just that extent had in reality defrauded her.

From what has been said so far, you are beginning to think this whole matter of functional tests is either unsatisfactory or impracticable. As a matter of fact this is probably true. If you do functional hearing tests on a patient and that particular work is to be checked, and you know it, you will probably do academic work, but if an unsuspecting patient has absolute confidence in you, and you are busy, you will probably treat him and put off the scientific examination from one time to another indefinitely.

At present I am doing functional hearing tests on every case of deafness that I examine or treat, and am repeating these tests at intervals regardless of the fact that the element of time is most distressing. To do otherwise is unfair to the patient and incidentally jeopardizes the security of my own judgment.

Briefly and in conclusion, the functional hearing tests are used in my office for the following reasons:

- 1 To differentiate and classify deafness
- 2 To record the condition of an individual case throughout duration of deafness
- 3 To determine percentages of disability
- 4 To adjust medico-legal and compensation cases
- 5 To assist in the localization of intra-cranial lesions

tained so that he has orthophoria by all tests has a stable equilibrium. In some the equilibrium is so unstable that they readily drift from a heterophoria into a squint. Such indications as these are of much more significance than the actual amount of deviation elicited. So far as symptoms go, those who have prompt and easy fusion control have much less disturbances than those with much less manifest deviation in whom the control is difficult or uncertain.

How far we should go in releasing the eyes from fusion control when making our tests is a matter of controversy. Marlow and others believe that we should in very many instances use occlusion of one eye for a week or so. The idea underlying this practice seems to be that such occlusion freeing the eyes from fusion control will reveal their true motor condition, in much the same way that cycloplegia under atropine reveals the true refractive state. I have already referred to what seems to me the fallacy involved in this analogy\*. When we thus employ occlusion for a week we do not reach the limit of release from fusion control as we do reach the limit of accommodative relaxation when we use atropine in a thorough-going way. The ultimate limit would be reached only by occlusion for many months, which if it had its full effect should produce dissociation of movements or a return to the early infantile state, in which it is said the eyes wander more or less aimlessly without reference to each other. This certainly would not represent the natural condition of the eyes, nor do I believe that the half-way emancipation produced by a week's occlusion represents it either. What such occlusion does effect and what may make it serve as a valuable indication in some cases is that it demonstrates how readily the eyes tend to escape from fusion control, and, when they escape, what special tendencies to deviation they exhibit. In this way the test may furnish a guide to operation. But even here caution is necessary. Prolonged occlusion is pretty sure to develop a convergence insufficiency which can be only regarded as artificial and which produces an exophoria marked for near and sometimes fairly considerable for distance as well. Such an insufficiency will disappear when fusion reasserts its control and is by no means necessarily an indication for operation.

On the other hand, such an artificial insufficiency may take some time to disappear and produce troublesome symptoms in the meantime.

For this reason I think the occlusion test for determining deviations should be used with circumspection and only in selected cases, and that the findings from it should be regarded only as a general guide. It would seem to me of much more value in vertical than in lateral deviations.

In the former, however, with the exact methods of analysis that we have—determination of the extent of the excursions of each eye in binocular movement and the determination of the deviation and diplopia in different directions of the gaze—it would not seem often required.

For a like reason I think that the practice at one time much employed of "developing" the full amount of a deviation by prisms is in general unsound. The idea underlying this procedure was that if a patient showed a moderate error—particularly a hyperphoria—we should correct this with a prism, and after he has worn this awhile, should test him again to ascertain if more error had developed. If it had, the prismatic correction was progressively increased until no more error was manifest. In some cases this procedure, which I tried repeatedly, seemed to me helpful, but there is always the risk that the patient will develop a condition quite artificial, particularly if he has good fusion power. I think in no case should this method be tried for a lateral deviation and but rarely for a vertical. This statement does not mean that I disbelieve in using a trial prism to ascertain if it relieves symptoms. The use of such a prism may give valuable indications for the subsequent treatment. But this is quite different from using a prism to "develop" a supposititious latent muscular error—a thing the very existence of which is problematical.

As opposed to the methods above considered I believe the most valuable tests of imbalance are those which produce only a moderate relaxation of fusion control and which thus indicate not only the tendencies of the eyes but also the relative ease with which the power that regulates and restrains these tendencies can be put out of gear. Thus a deviation which is made manifest at once by putting on a red glass is of more significance and is more directly in need of relief than one which shows no diplopia by this means and is rendered apparent only by the screen test or Maddox rod. Again, a deviation shown by the screen, which is of large amount but is instantly and easily redressed when the screen is removed is of less moment than one of much smaller amount which is overcome with difficulty, or at times, not at all.

In any case, the tests for imbalance, however made, must, as already said, be supplemented by tests which show how well the eyes are possessed of the means that enable them to effect fusion in all directions and ranges of the gaze. I mean that they must be supplemented by tests which indicate the ability of the eyes to keep pace with each other in each of the six primary directions of the gaze and the tests for convergent and divergent movement. These tests, indeed, are more important than the tests for imbalance per se. For the diagnosis and for the determination of the means that should be used to remedy the motor disturbances they are in fact essential.

\*Mr. Justice to Dr. Martin. I should say that he does not maintain that this analogy holds completely.

imposing any constraint on the eyes we look straight ahead at a distant object, each eye is held in place not by mechanical, unchanging conditions, but by the simultaneous contraction of all six of its muscles, each acting as a counterpoise to its opponent. These muscles in turn are made to contract to just the right extent by reflex stimuli set up by visual and muscular impulses acting through the coordinating nerve centres. The position of the eyes thus represents the balance of opposing varying forces, which are coordinated and regulated by the demands of fixation. These demands themselves are sometimes more sometimes less imperious, so that this controlling power necessarily varies from time to time. With all this interplay of compelling forces and muscular tensions it is no wonder that in many cases the findings as to the position of the eyes vary. Such a variation will be particularly likely to occur if we introduce factors that tend in varying degree to break up fusion control, and this we do in many of our tests (screen, phorometer, Madox rod). Nor when such variation occurs are we in position to say which finding represents the absolute state of the muscle balance. For, indeed, there is no such absolute state. When a man one day rejects a glass and the next day accepts a +1D, we do know that his static refraction is a hyperopia of at least 1D and we also know that by instilling atropine we can arrive at a true measure of what his refractive state is. But if a person shows orthophoria one day and on another day when his efforts are more relaxed an exophoria of  $6\sqrt{\phantom{x}}$ , we cannot by any means necessarily infer that the true state of his muscle balance is represented by a divergence of the visual axes of  $6\sqrt{\phantom{x}}$  or over. All that we can say is that he has a tendency to divergence which at times when the fusion control is good is reduced to nothing, at other times when the fusion control is less strong amounts to at least  $6\sqrt{\phantom{x}}$ . But note that when he does show the  $6\sqrt{\phantom{x}}$  of deviation this is generally due to the introduction of some non-natural and unusual condition, e.g., the application of some test that reduces the fusion control. If such tests are pushed further, so that fusion control is largely lost, then the moderate exophoria in such a case is turned into a large and temporarily incorrigible squint. We see instances of this when the patient has been subjected to prolonged monocular occlusion or has in other ways shunted off one eye, e.g., by prolonged use of the monocular microscope. And if the suspension of fusion control were pushed to its extreme, i.e., to the point of absolute and permanent abolition, then every person, even though originally orthophoric, would show not simply a deviation of the eyes but a complete dissociation. Such a condition could not by any possibility be regarded as representing the real state of the eye balance, nor could we say that any of the intermediate conditions caused by partial

suspension of the fusion control represented it precisely either.

One further consideration. When we abolish the accommodation with atropine, we have, as has been said, a perfectly fixed and determinate condition to deal with, namely, the refractive state conditioned by two unvarying factors—the curvature of the media and their optical density. But if we should succeed in absolutely abolishing fusion control, we would have no like stable condition to measure, i.e., no mechanically fixed position of the eyes, but an anarchy of opposing and continually varying, entirely unregulated muscular tensions, causing the eyes to wander aimlessly and more or less independently first in this direction, then in that.

A motor anomaly is thus fundamentally different in character from an error of refraction. A refractive error, being due to structural defects is unchangeable except as the result of comparatively slow alterations taking place in the shape of the eye itself. It is thus a substantive, unchanging entity. Its amount is definite and determinable, being represented by the highest measurements obtained on the use of the most thorough-going and prolonged tests (atropine). A motor anomaly, being due to the balancing of forces, is something essentially variable in its nature. It may remain approximately constant, provided the conditions under which the balancing forces are applied remain the same, but it changes as soon as these conditions are radically altered. It has no definite assignable amount, and the maximum values of it obtained by the most thorough-going methods of examination (prolonged occlusion) cannot be regarded as its true measurement but simply indicate the greater or less stability of the controlling forces and the tendencies that the eyes develop when these controlling forces are relaxed.

The most we can do is to determine whether the controls that keep the eyes from deviating are performed easily, habitually, and without nervous wear and tear, or, on the other hand, whether the eyes frequently or usually escape from them and hence deviate. When they do deviate we can measure the amount of the deviation, yet even then cannot say that in so doing we measure the motor anomaly in anything like the sense that in determining the refraction we measure a refractive error.

All this has a direct bearing on the significance of the tests used in measuring motor anomalies. As above stated, many of these tests act by breaking up fusion control, and some do this in a more thorough-going way than others and sometimes therefore afford different findings. These differences are of considerable clinical significance. We may say that a person whose fusion control is readily broken up by even a momentary application of the screen test has an unstable, and one in whom the control is more stoutly main-

larged thyroid The basal metabolic rate was +38% in one and +69% in the other, exophthalmos was present in one instance Surgery was necessary in both and the pathological report on the gland was hyperplasia in each case Although this occurrence is rare under age 20 it illustrates the necessity of direct supervision by a physician of all goiter cases taking iodine Over age 20 iodine should be given for simple goiter with even greater care because of the ever present possibility of an adenoma being present which may be rendered toxic by iodine Collier<sup>7</sup> has shown that after age 25 most simple goiters contain some adenomatous tissue the ratio of which to colloid increases so that after age 30 the adenomatous element dominates the picture In other words the simple goiter of age 25 becomes the adenomatous goiter of age 45 It is for this reason that iodine treatment should not be given for simple goiter over age 30

#### ADENOMATOUS GOITER

The adenomatous or nodular goiter comprises nearly all the non toxic goiters occurring over age 30 This group show a normal basal metabolic rate Here iodine is contra-indicated because it may change the picture to one of adenomatous goiter with hyperthyroidism This danger of iodine in the presence of an adenomatous thyroid has long been known but has seemingly been forgotten in the recent enthusiasm for the drug It is probably here that the indiscriminate use of iodine has done the most harm and where iodized table salt and drinking water have their danger Because of the fact that a high percentage of this group become toxic in middle life the surgical removal should be urged of all adenomatous goiters over age 30

#### EXOPHTHALMIC GOITER

In exophthalmic goiter the use of iodine was formerly thought to be extremely dangerous but since introduced recently by Plummer,<sup>8</sup> its use has become generally accepted as preoperative preparation in this group It is certainly remarkable to see these desperate risk cases change in 10 days to mildly toxic ones at which time subtotal thyroidectomy may be done at little or no risk Iodine preparation has now rendered the many stage operations obsolete and makes surgery possible in many cases that formerly died before an operation could be attempted At present in this group pole ligation has been reduced by this procedure to less than 10% while upward to 90% of the cases are operated in one stage Cattell<sup>9</sup> found that after a course of iodine the hyperplastic gland shows an involution change the high columnar epithelium changes to cuboidal and then to flat also there is an

increased deposition of colloid making the gland very friable In exophthalmic goiter iodine brings about a remission in from 8 to 21 days which is evidenced by marked clinical improvement and a lowering of the basal metabolic rate to normal or near normal At this point if the drug is discontinued Starr<sup>10</sup> has shown the metabolic rate will quickly rise again and even if the drug is continued the rate will amount to its former level in a few weeks Hence it becomes clear why iodine should not be used as medical treatment for exophthalmic goiter It is in this group that iodine is at present being used most unwisely It seems to be general practice where ever hyperthyroidism is suspected to prescribe iodine without any thought of its action A patient diagnosed as toxic without a metabolism test is given iodine for a time and then sent to the surgeon A metabolic study now reveals a normal rate and the question arises is this due to iodine or was toxicity present in the beginning As there is generally great doubt the iodine must be withdrawn for some weeks and if the rate does not rise the diagnosis was wrong All this confusion could be avoided by making the diagnosis certain with a metabolism test before giving iodine Because the first remission is always the most complete the drug should never be given until consent for operation has been obtained and the patient confined to a hospital The surgeon should always see the case before giving iodine otherwise he will have no conception of the original state of the patient The average dosage is 15 to 30m of Lugol's solution daily depending on the severity of the case as indicated by the basal metabolic rate Metabolism estimations are made at frequent intervals until the rate is normal or ceases to fall when this optimal time is reached generally in from 8 to 21 days subtotal thyroidectomy may be done in one stage with little risk Unless this procedure is carried out it will be very easy to miss the point at which the metabolism is lowest and the best time for operation will be lost In the high initial rate cases and where the rate cannot be lowered to +35% the removal may be done in two stages To avoid a crisis the drug must be given on the day of operation by mouth or rectum If the operative reaction is marked the daily dose should be doubled and if a crisis develops 60 to 100m, or more of Lugol's solution must be given The preoperative dose should be continued for about 10 days after operation A small percentage less than 10 of this group fail to respond to iodine and in these cases the former methods of stage surgery must be resorted to This modern method of managing exophthalmic goiter is of great economic importance because it shortens the patient's period of disability by several weeks

## THE VALUE AND DANGER OF IODINE IN THYROID DISEASE\*

By MAYNARD E. HOLMES, M.D., SYRACUSE, N. Y.

**I**ODINE has always been used in the treatment of goiter. During the past few years, however, its employment has markedly increased due to numerous reports in the literature dealing with the value of iodine in certain definite types of thyroid disease. It is only natural perhaps that the enthusiasm stimulated by these reports should lead to the widespread giving of iodine not only in the limited group recommended but in all types of thyroid disease where in one case it relieves and in another case does real harm. This confusion is in part due to lack of appreciation of the fact that iodine is only of value in a limited group of thyroid abnormalities and the neglect of correctly diagnosing the type of thyroid disease present.

Formerly the diagnosis of hyperthyroidism was most uncertain and because of this it was often confused with various functional neurotic states where the thyroid was often needlessly removed with excellent mortality statistics. Likewise numerous drugs and modes of treatment were advocated as cures for toxic goiter all of which are now known to be worthless. The introduction of basal metabolism studies has changed all this and has placed the whole subject of thyroid disease on a definite scientific basis.

Thyroid disease is divided into two great groups the non toxic which are characterized by a normal or lowered basal metabolism and the toxic which are characterized by an increased basal metabolism. To the non toxic group belong the simple colloid and the adenomatous goiter, to the toxic group belong the adenomatous goiter with hyperthyroidism and the exophthalmic goiter. Before iodine is given in any goiter a definite diagnosis should be made, is it toxic or non toxic, is it colloid, adenomatous or exophthalmic? Until this is done there is danger and confusion from the use of iodine. It is my purpose here to outline briefly according to our present knowledge in what types of goiter iodine is of value and in what types it should be avoided.

### GOITER PROPHYLAXIS

Goiter is only present in certain parts of the world where there is a deficiency of iodine in the drinking water. In this country the goiter belt comprises the great lake States and the northern and central western States. Goiter is rare in New England and the southern States. In this belt are found according to McClendon<sup>1</sup> most of our toxic and non toxic goiters. In this area Marine and Kimball<sup>2</sup> have clearly shown that small amounts of iodine properly given to children will prevent the development of

adolescent or simple goiter. Several methods of giving the drug have been advocated, in table salt, drinking water and various doses by mouth. Of these the one with the fewest drawbacks is that of giving 10 mg. of iodine per week throughout the school year from age 10 to 17. Convenient palatable tablets containing 10 mg. of iodine are made for this purpose. Kimball<sup>3</sup> states that one of the most important phases of the whole goiter problem is the prevention of congenital goiter from which most adenomatous goiters arise. He advises that the giving of 10 mg. of iodine weekly during pregnancy and lactation will prevent the development of goiter in the mother and insure a normal thyroid in the child. Goiter prophylaxis is indicated only in goitrous areas. Cohen<sup>4</sup> in a recent survey found that this is unnecessary in New York City.

### SIMPLE COLLOID GOITER

The adolescent or simple colloid goiter usually appears between the ages of 10 and 15, six times more often in girls. This type is non toxic and has a normal basal metabolism. Except in rare instances of extreme enlargement it is not a surgical condition. Often in the past however, simple goiter was erroneously diagnosed as toxic because of the accidental presence of tremor, tachycardia, nervousness, fatigue or emotional instability, all of which may be of functional neurotic origin. This error is now inexcusable because a basal metabolic test will quickly clear up the diagnosis. If the basal metabolic rate is found to be normal hyperthyroidism is not present. Simple goiter under age 20 can be cured or markedly relieved in the majority of instances with minute doses of iodine properly given.<sup>5</sup> Kimball<sup>6</sup> advises 10 mg. daily during alternate months. The maximum improvement may not occur for several months and at this point the dose should be decreased to 10 mg. weekly. The painting of the goiter with iodine or the rubbing into the gland of iodine ointment should be abandoned for the accurate oral administration of the drug. Marine<sup>7</sup> has also suggested the use of small doses of thyroid extract in conjunction with iodine for the treatment of this group, and I have found it very helpful in refractory cases. Iodine should not be given where goiter is present unless the patient is kept under the close observation of a physician because occasionally a case may be rendered toxic. I have seen two such cases in school children who developed symptoms of toxicity after taking small doses of iodine over a period of from 3 to 6 months for an en-

\* From the Department of Medicine, Syracuse University.

larged thyroid The basal metabolic rate was  $+38\%$  in one and  $+69\%$  in the other, exophthalmos was present in one instance Surgery was necessary in both and the pathological report on the gland was hyperplasia in each case Although this occurrence is rare under age 20 it illustrates the necessity of direct supervision by a physician of all goiter cases taking iodine Over age 20 iodine should be given for simple goiter with even greater care because of the ever present possibility of an adenoma being present which may be rendered toxic by iodine Collier<sup>7</sup> has shown that after age 25 most simple goiters contain some adenomatous tissue the ratio of which to colloid increases so that after age 30 the adenomatous element dominates the picture In other words the simple goiter of age 25 becomes the adenomatous goiter of age 45 It is for this reason that iodine treatment should not be given for simple goiter over age 30

#### ADENOMATOUS GOITER

The adenomatous or nodular goiter comprises nearly all the non toxic goiters occurring over age 30 This group show a normal basal metabolic rate Here iodine is contra-indicated because it may change the picture to one of adenomatous goiter with hyperthyroidism This danger of iodine in the presence of an adenomatous thyroid has long been known but has seemingly been forgotten in the recent enthusiasm for the drug It is probably here that the indiscriminate use of iodine has done the most harm and where iodized table salt and drinking water have their danger Because of the fact that a high percentage of this group become toxic in middle life the surgical removal should be urged of all adenomatous goiters over age 30

#### EXOPHTHALMIC GOITER

In exophthalmic goiter the use of iodine was formerly thought to be extremely dangerous but since introduced recently by Plummer,<sup>8</sup> its use has become generally accepted as preoperative preparation in this group It is certainly remarkable to see these desperate risk cases change in 10 days to mildly toxic ones at which time subtotal thyroidectomy may be done at little or no risk Iodine preparation has now rendered the many stage operations obsolete and makes surgery possible in many cases that formerly died before an operation could be attempted At present in this group pole ligation has been reduced by this procedure to less than 10% while upward to 90% of the cases are operated in one stage Cattell<sup>9</sup> found that after a course of iodine the hyperplastic gland shows an involution change, the high columnar epithelium changes to cuboidal and then to flat also there is an

increased deposition of colloid making the gland very friable In exophthalmic goiter iodine brings about a remission in from 8 to 21 days which is evidenced by marked clinical improvement and a lowering of the basal metabolic rate to normal or near normal At this point if the drug is discontinued Starr<sup>10</sup> has shown the metabolic rate will quickly rise again and even if the drug is continued the rate will amount to its former level in a few weeks Hence it becomes clear why iodine should not be used as medical treatment for exophthalmic goiter It is in this group that iodine is at present being used most unwisely It seems to be general practice where ever hyperthyroidism is suspected to prescribe iodine without any thought of its action A patient diagnosed as toxic without a metabolism test is given iodine for a time and then sent to the surgeon A metabolic study now reveals a normal rate and the question arises is this due to iodine or was toxicity present in the beginning As there is generally great doubt the iodine must be withdrawn for some weeks and if the rate does not rise the diagnosis was wrong All this confusion could be avoided by making the diagnosis certain with a metabolism test before giving iodine Because the first remission is always the most complete the drug should never be given until consent for operation has been obtained and the patient confined to a hospital The surgeon should always see the case before giving iodine otherwise he will have no conception of the original state of the patient The average dosage is 15 to 30m of Lugol's solution daily depending on the severity of the case as indicated by the basal metabolic rate Metabolism estimations are made at frequent intervals until the rate is normal or ceases to fall when this optimal time is reached generally in from 8 to 21 days subtotal thyroidectomy may be done in one stage with little risk Unless this procedure is carried out it will be very easy to miss the point at which the metabolism is lowest and the best time for operation will be lost In the high initial rate cases and where the rate cannot be lowered to  $+35\%$  the removal may be done in two stages To avoid a crisis the drug must be given on the day of operation by mouth or rectum If the operative reaction is marked the daily dose should be doubled and if a crisis develops 60 to 100m, or more of Lugol's solution must be given The preoperative dose should be continued for about 10 days after operation A small percentage less than 10 of this group fail to respond to iodine and in these cases the former methods of stage surgery must be resorted to This modern method of managing exophthalmic goiter is of great economic importance because it shortens the patient's period of disability by several weeks

## ADENOMATOUS GOITER WITH HYPERTHYROIDISM

Adenomatous goiter with hyperthyroidism is the nodular goiter of many years standing which in middle life takes on the symptoms of hyperthyroidism with an elevated basal metabolism. This group tend to marked cardiovascular damage and because of this many become bad operative risks before the correct diagnosis is made. These cases are often treated for cardiac disease and hypertension until a metabolic study reveals the underlying primary condition. Preoperative iodine preparation in this group is generally not advocated, however. I have used it as in the preceding group and have obtained somewhat similar results. The rate declines 15 to 30 points but frequently does not reach normal. This action may be due to the presence of some hyperplasia about the adenomata in other words a mixed type of hyperthyroidism exists. Mason<sup>11</sup> and Graham<sup>12</sup> have reported similar observations. The diffuse adenomatosis type seems to be more responsive to iodine than the true adenoma. Iodine is contra-indicated in this group as medical treatment. Surgery is the only treatment for toxic adenoma and where the diagnosis is made early the risk is slight and results are excellent.

## IODINE HYPERTHYROIDISM

Iodine or induced hyperthyroidism is a term given to that type of thyroid toxicity which is induced by iodine. It is this condition which in the past has made iodine a much feared drug in toxic goiter. Jackson<sup>13</sup>, Kimball<sup>6</sup> and Hartock<sup>14</sup> have recently called attention to the alarming increase in this condition during the past 2 years due apparently to the increasing use of iodine in goiter particularly in the form of iodized table salt. The symptom complex may be that of either adenomatous or exophthalmic hyperthyroidism, most of the cases I have seen have resembled the latter type. The pathological examination reveals generally a gland of the adenomatous type but in some of my cases only hyperplasia was found while in others the picture was that of adenomatosis. If an early diagnosis is made and the drug withdrawn the toxicity may subside but in most instances surgery must be resorted to.

## CONCLUSIONS

1 Where goiter is present iodine should be given in minute doses, prolonged courses of the drug should be discouraged, it should always be administered with caution and always under the direct supervision of a physician.

2 Iodine as medical treatment is contra-indicated in adenomatous goiter and in any goiter over age 30.

3 Iodine will not cure exophthalmic goiter or adenomatous goiter with hyperthyroidism hence should not be used as medical treatment for either.

4 In exophthalmic goiter iodine should not be given until a basal metabolism test has made the diagnosis certain and the consent for operation has been obtained.

## HYSTEROPLASTY FOR THE CONSERVATION OF MENSTRUATION— PRELIMINARY REPORT\*

By S. DI PALMA, M.D., F.A.C.S., NEW YORK, N. Y.

**T**HE writer, in view of sad sequelae from supracervical hysterectomies performed for uterine fibroids on patients under 35 years of age, decided to experiment on a technique which would conserve the menstrual function.

It is a known fact that if the body of the uterus is amputated at the cervix, although the ovaries are retained, menstruation ceases, as the mucosa of the cervix takes no part in this process. It is also definitely known that the ovaries, in a comparatively short time, become inert in regard to internal secretion, and in a large number of cases while an artificial menopause may be delayed, nevertheless it occurs.

In a certain number of cases a high supracervical hysterectomy, as advocated by Novak, may be and should be performed. However, my idea was to devise a procedure in myoma uteri by which one could conserve the menstrual function practically in all cases in which supracervical hysterectomies are performed during the child-bearing period when one or both ovaries are preserved.

In the cases referred to in the beginning of this report, although the ovaries were conserved, menopausal symptoms developed 2 to 3 months after the operation. These were manifested by hot flushes, palpitation, dizzy feelings, nervous irritability and a tendency to mental depression. The neuro-psychic symptoms were most pathetic. Treatments have been of no avail. One patient, five years after the operation, continues to have periods of depression manifested by crying spells, lack of appetite, hyperaesthesia, etc. She is very intelligent, realizes her condition, as she expresses it "I combat these feelings as much as I can, but they are stronger than my will." Whenever she gets in such a depressed state she avoids company, plainly showing that they are beyond her control.

If, in these women, the menstrual function had been preserved, vaginal bleeding recurring as before, the menopause would not have followed, and years of their lives would not have been made miserable.

In order to successfully retain menstrual function it is necessary to preserve the blood supply of at least one ovary and a portion of the endometrium. It is also essential to leave in the uterine stump as much mucosa as possible, the duration and quantity of the subsequent menstruation, I find, depends upon the amount of the uterine mucosa retained.

The following is a description of the technique adopted by the writer. It may have to be modified according to the discretion of the operator.

After the abdomen is opened and the uterus is discovered to be the seat of multiple fibromyomata in which enucleation is not possible or not feasible, instead of the usual supracervical hysterectomy, I proceed as follows. Two clamps are placed on each side of the uterus including the round ligaments, the tubes, the utero-ovarian ligament and the broad ligament. The structures are cut between the two sets of clamps and the broad ligament is split. The anterior leaf is cut downward on each side of the uterus to about the junction of the lower and middle thirds of the uterine mass, and the uterine arteries are ligated or clamped at this site. The posterior leaf of the broad ligament is then incised in a downward and inward direction to the point where the uterine artery has been clamped. At this level the mass is cut across to the endometrium (Fig 1).

Fig 1—The Amputation

As much as possible of the mucosa is dissected out above the line of incision. If fibroid growths are encountered in cutting the uterus to its cavity they are either enucleated, if possible, or sectioned across.

The amputation of the uterus is continued so that when it is finished we have. About the lower third of the uterine body with its mucosa intact,

\* Read at the Annual Meeting of the Medical Society of the State of New York at New York March 30 1926

Fig 2—Top of the stump of the uterus

Fig 3—Enucleating the fibroids in the stump

Fig 4—Obliterating the seats of the fibroids

Fig 5—Closing the broad ligament over the stump

besides a certain amount of mucosa originally belonging to the amputated upper two-thirds, one, or possibly several sectioned fibroids in the musculature of the lower uterine third (Fig 2) On account of the several branches of the uterine arteries which traverse the uterine musculature below its ligation, some bleeding is apt to occur This is controlled in the usual manner The sectioned fibroids are then enucleated (Fig 3) Digital exploration is made to ascertain whether more growths are present Dead spaces are obliterated (Fig 4) The loose mucosa is invaginated in the remaining uterine cavity The uterine aperture is closed by a purse string suture, and the operation is completed as in the usual supracervical hysterectomy, the broad ligament stump being sutured over the retained uterine segment (Fig 5)

The possible objections to this operation are, 1st, the length of time, 2nd, difficulty of technique, 3rd, possibility of leaving in small unpalpable fibroids

It is true that this technique takes about double the time of the usual hysterectomy However, in most instances, the patient is well able to stand it being in the prime of life It is needless to say that this operation should not be performed by any one but an experienced operator There is a possibility of leaving in small unpalpable fibroids, but what of it A later myomectomy is always in order in case they grow to give symptoms

The writer has performed 8 of these operations in the Gynecological Department of the Harlem Hospital, Dr Cherry's Service The patients had large uteri filled with fibroids varying in size from a small pea to about 10 x 12 cm, the average uterine body being about 16 x 20 cm In these cases a high supracervical hysterectomy has been deemed unfeasible to date and a myomectomy out of the question (Fig 6 and 7)

The following 3 cases are brief reports in which the above described operation was performed

G A, Age 40 years, admitted to Dr Cherry's Service, Harlem Hospital, Apr 8, 1925

Menstrual History started at 13 years, every 30 days, for 3 days Did not miss any periods She has had pre and co dysmenorrhea

CC Enlargement of abdomen, pain in lower abdomen, prolonged menstruation, 4-6 days

Diagnosis—Multiple Uterine Fibroids

Operation—Hysteroplasty as described, May 1st, 1925 The uterus in this case was transformed into an irregular mass 15 x 18 cm On the right side of the uterus was a pedunculated calcified mass One tube and ovary removed In performing the operation three small fibroids were bisected and were enucleated from the lower uterine segment

Discharged May 17th, 1925, after an uneventful recovery

Follow up Notes June 6th, 1925, patient re-

ported that she had menstruated during the previous week, lasting 3 days Pelvic examination, negative

July 11th, 1925, patient reported last period June 27th, for 3 days, no clots, no pains Abdominal wound well healed Pelvic examination, negative

August 12th, menstruation on July 28th, for 3 days

The Social Service Worker called at the patient's house in September and was informed that

Fig 6—Type of myoma in which a supracervical hysterectomy is almost invariably performed

the patient had gone to Pittsburg and had left no address

Case No 2—O B, Age 36, Admitted to Dr Cherry's Service, Harlem Hospital, June 19th, 1925

Menstrual History Onset 19 years, lasted 4-5 days, every 30 days, no accompanying symptoms Continued regularly up to the present illness Menorrhagia periods are now extended from 7 to 8 days, and often longer These started 6 months ago with occasional dysmenorrhea She has never missed a period Last period, June 4th (8 days)

CC Enlargement of the abdomen, dysmenorrhea, metrorrhagia, duration 6 months

Diagnosis Multiple Uterine Fibroids

Operation June 12th, 1925 Hysteroplasty as described Both tubes transformed into a hydrosalpinx Both tubes removed Both ova-

rics conserved Several section fibroids were found in the lower third of the uterus Patient developed post-operative Phlebitis  
Discharged July 17th, 1925

Fig 7—Type of myoma in which a supracervical hysterectomy is almost invariably performed

Follow-up Notes Patient reported to clinic on August 22, 1925, as having her menstrual period starting on August 10, for 3 days, moderate amount of blood and little pain Pelvic examination, negative

September, 1925 Menstruated for 6 days

Social Service Department has been unable to locate patient, so that I am unable to report further on this case

Case No 3 E. C., Age 31 years, Admitted to Dr Cherry's Service, Harlem Hospital, April 27, 1925

Menstrual History Started at 15 years, every 30 days, for 4-5 days Last period, April 12 to 17 previous period just one month before

CC Enlargement of the abdomen and pain in R L Q

Diagnosis 1 Fibroid Uterus

2 Ovarian Cyst (?)

Operation Hysteroplasty as described April 29th, 1925

Uterus was found to be converted into a globular mass about 20 x 16 cm

In the amputation of the upper two-thirds of the mass a small piece of fibroid tumor was left in the lower uterine segment This was enucleated Both ovaries were conserved Patient made an uneventful recovery

Discharged May 16th, 1925

Follow-up Notes First menstruation, June 6th, dark fluid blood

July 11th, patient menstruated for 10 days, no clots Pelvic examination negative

March 15th, 1926 Patient states that she has menstruated every month since operation, without any pain, bleeding from 3 to 5 days No menopausal symptoms General condition, excellent Vaginal examination, negative, remnant of uterus, anterior freely movable

It is too recent a date to report on the other 5 cases, as they were only operated during the months of February and March, 1926 However, one of the patients menstruated during her convalescence while still in the Ward

Conclusion Enough time has not elapsed to formulate definite conclusions However, it seems from these case reports quite evident that the operations performed on these patients, with the view of preserving the menstruation and the prevention of menopausal symptoms, accomplishes the intended result Any unbiased physician must thoroughly agree with Bell who states, "The preservation of the genital function in the female, even though conception be impossible, is a surgical ideal to which we should strive to attain whenever operation on the female genitalia is necessary," and with Wm H Mayo, "I would reiterate that the conservation of the menstrual function is of the utmost importance even if pregnancy is not possible, and that the surgeon who faces the necessity of removing the ovaries or the uterus and bringing about all those endocrine changes attending the procedure, is taking a serious responsibility which must not be assumed lightly"

## THE IMPORTANCE OF THE EARLY RECOGNITION OF UROLOGIC PATHOLOGY\*

By HENRY G. BUGBEE, M.D., NEW YORK, N. Y.

**T**HREE types of lesions of the urinary tract may be eliminated or controlled if recognized in their early stages yet are fatal if allowed to progress. They are malignancy, tuberculosis and prostatic obstruction.

While other types of malignancy are found rarely, carcinoma is the growth which may involve the mucous membrane lining any part of the urinary tract, the sex glands (testes and prostate) or the kidneys. The frequency of its incidence is being appreciated more and more through the accuracy of urological diagnosis brought about by cystoscopy and urography. Our hope for the future lies in our ability to get these cases in their incipency which means the recognition of the earliest signs and symptoms by the general practitioner and their referring them to the urologist for his study until the presence or absence of a new growth is established. Carcinoma of the urinary tract occurs most frequently in the bladder, next in the prostate, and next in the kidney. A large percentage of bladder carcinomata originate as a papilloma which may cause no symptoms for years until a sudden attack of hematuria leads to a cystoscopic examination and its presence is discovered.

Sad to relate, patients are often brought to us by a physician with the statement that possibly three or four years previously they had passed a little blood but the bleeding had stopped readily with or without medication, or, the patient may not have even consulted a physician. The papilloma which could easily have been eradicated has become a malignant growth which may be incurable.

Tumors of the bladder seldom cause symptoms early in their existence but sooner or later give rise to the presence of blood cells in the urine which may for a long time be microscopic, or a true hematuria may give the first inkling of their existence.

Periodical urinalysis demonstrating the presence of microscopic blood cells, or an attack of hematuria, should always lead one to suspect a tumor of the bladder—and calls for a cystoscopic examination, bearing in mind the fact that a benign papilloma may be eradicated by fulguration while the possibility of a cure in malignancy is diminished with each day it is allowed to remain.

Frequency and dysuria are late symptoms in bladder tumors.

Carcinoma of the prostate occurs in about 15 per cent of all men seeking relief from prostatic obstruction. Unfortunately the process originates in a part of the gland that is little

involved in urinary function and extends but late to those parts of the gland that give rise to urinary symptoms. The habit of making a rectal examination on all males as a part of a physical examination will however make it possible to detect irregularities, induration and fixation of the prostate in an occasional case at a time when operation or radium might be employed with a hope of eradicating or arresting the growth, giving the patient years of life and comfort, while detection of the pathology when retention has taken place probably means that measures tending to relieve the patient's suffering is all that can be hoped for.

A charming old gentleman of 74 recently came to see me in great distress, complaining of extreme frequency and dysuria which he dated back but three weeks. Careful questioning, however, revealed the fact that he had been under treatment at intervals for pains in the groins and legs over a period of several years. He had been told that to urinate once or twice a night was quite normal for a man of his years and only the day before I saw him, had a rectal examination been made. The prostate in this case was the seat of a carcinoma which had extended to the rectal wall and to the pelvic bones on either side.

Prostatic calculi may easily stimulate a new growth but an X-ray readily demonstrates their presence.

Until urography with the careful study of pyelograms became a more common practice, tumors of the kidney were seldom diagnosed until the disease was so far advanced that nephrectomy offered little more than a temporary relief if indeed it was possible at all.

Now with reference to the urologist of early cases of hematuria and occasionally of patients whose urine shows the presence of microscopic blood cells—we are finding tumors of the kidney much more often and at a time when nephrectomy means a cure. In the absence of a tumor of the lower urinary tract or the presence of a calculus or infection of the upper urinary tract, the persistence of blood cells in the urine must be looked upon with suspicion as possibly pointing to a renal tumor.

During the past two years the writer has operated eight cases of renal tumor in four of which only microscopic blood cells were found in the urine. Repeated observations and pyelograms were necessary to demonstrate an increasing filling defect of the kidney pelvis by which means the diagnosis was made, resulting in an early nephrectomy. In only three very recent cases was a tumor mass palpable. In a fourth the kidney was palpable, and here

\* Presented before the New York County Medical Society, January 24, 1927.

due to a prolapse of the organ, X-rays showing no increase in the size of the kidney outline

If one waits for a frank hematuria and a tumor mass, the time has probably passed in which one may expect a cure through operation. Periodical cystoscopic examinations should be made following an apparently successful operation for malignancy, even though there are no signs or symptoms indicating a recurrence of the growth

Spontaneous frequency of urination, dysuria and pain in the perineum or urethra following urination, in young adults, should be looked upon with suspicion as indicating tuberculosis of the urinary tract. Yet I have seen cases in which these symptoms were negligible but repeated observations instigated by the finding of pus cells in the urine have led to a positive diagnosis

While in many instances the history of a tuberculous process elsewhere in the body may be obtained, or such an active focus may be present, yet in others the original focus may have been overlooked

I have been much impressed with the increasing alertness with which the urinary tract is being watched by specialists in treating cases of pulmonary and general tuberculosis. These men are apparently awake to the frequency of renal involvement, its importance as a vital factor in turning the scales toward recovery, and the possibility of its cure when discovered early in its existence

The pathology of renal tuberculosis is such that it is often one of the most difficult of all urinary diseases to diagnose. I speak of urinary tuberculosis as renal tuberculosis as only in a very small percentage of cases is the urinary process primary outside of the kidney

That rarely tubercle bacilli filter through the kidney leaving very little if any kidney destruction, that minute tuberculosis of the kidney is more often bilateral than was at one time believed, has been proven by recent investigations. These however are not the usual courses of the disease. Tubercle bacilli lodge in the parenchyma of the kidney and often cause extensive destruction of the kidney before such foci break through into a calyx and secondary deposits take place in the pelvis, ureter and bladder, with the onset of the distressing urinary symptoms before mentioned. The body possesses remarkable resistance to tuberculous foci as shown by its efforts and often success in walling off such processes so that the discharge of tubercle bacilli, pus and blood from the kidney is intermittent and the urinary symptoms are correspondingly so

The first symptom of renal tuberculosis may be a rather profuse hematuria. This occurs when the focus is in a renal papilla with early ulceration through into a calyx

It is not my purpose to elaborate the technique of the diagnosis of urinary tuberculosis. The possibility of such a focus must be borne in mind when persistent frequency and dysuria are present or pus and blood cells are found in the urine and the patient should be referred to a competent urologist

Patience must be exercised in arriving at a diagnosis, for cystoscopic manipulation may be difficult, the findings misleading, and repeated observations over a period of time necessary to correctly interpret the pathology and outline the proper course of procedure

The following case, still under observation, presents so many phases of this disease that I wish to briefly mention the salient facts

A girl 18 years of age gave a history of tuberculous cervical adenitis as a child, of continued poor health, and for two months of frequent painful urination, with great distress in the perineum at the end of urination. She was poorly nourished, still had large cervical lymph nodes. Her lungs gave no positive signs of active tuberculosis but there were numerous areas of fibrosis. The systolic blood pressure was 75, digestion poor, and intestinal activity decidedly sluggish. Under general medical treatment, open air, nourishing diet, improved elimination and free administration of santol oil, the urinary symptoms subsided and a cystoscopic examination was possible. The bladder showed extensive tuberculosis. The right ureter was catheterized with difficulty owing to several constrictions, and the kidney specimens and pyelogram showed extensive tuberculous involvement on this side, the function being one-fifth that of the left, the left kidney however being the seat of a colon bacillus pyelonephritis. Under continued systematic treatment this patient steadily improved so that after a period of four months the bladder was practically clear of tuberculosis, the right ureter was easily catheterized, no tubercle bacilli were found in the urine, and the colon bacilli had disappeared from the urine on the left side. The function of the right kidney was now one-third that of the left. The blood pressure averaged over 90. She had gained 25 lbs. Under regular observations this improvement has been maintained

I do not cite this case as one of cured tuberculosis of the kidney, or as an argument against nephrectomy, but as showing the remarkable reparative power of nature which should be utilized to the fullest, as demonstrating the patience necessary in arriving at a diagnosis, and of the necessity of continued observation

Renal tuberculosis is progressive in its pathology and with the usual destruction of kidney tissue, pockets form which drain poorly, and often become the seat of pyogenic infections which later give rise to symptoms. Long per-

iods of quiescence are possible and a lighting up of the acute process may take place at any time. However, in this case nephrectomy at the outset would have carried with it a high degree of mortality, while if operation now becomes necessary we will have a good operative risk. The operation may be carried on in two stages in the occasional case where the removal of a large pyonephrosis in one stage would involve a decided risk.

If the general practitioner realizes that patients are to be studied in a careful painstaking manner and not rushed into an operation, I am sure they will be more ready to have the proper investigations carried out and the end results in renal tuberculosis which have already vastly improved will be increasingly more satisfactory.

The importance of prostatic obstruction with its secondary pathology in the urinary tract and its bearing upon the vital body functions, its distressing symptoms and its operative relief are pretty thoroughly understood today, yet how many of these patients are brought to us when retention is complete and the system is thoroughly undermined through impaired renal function and its secondary effects.

Changes in the prostate resulting in disturbances of urinary function begin to take place in middle life, at a time when man begins to lead a more sedentary life, the urine is more irritating and changes in the sexual life of the individual are common. These factors lead to congestion, which is the first stage of hypertrophy. At this stage of prostatic hypertrophy the symptoms are negligible and future progress is in most instances so slow and the onset of symptoms so gradual that they are often overlooked by the individual.

The importance of this stage is being appreciated more often however, for I frequently have men sent to me who have never noted any urinary symptoms but who say that their doctor in the course of a physical examination had made a rectal examination and stated that the prostate was enlarged.

Measures tending to reduce prostatic congestion including regulation of diet, general hygiene, improved elimination and mild local treatment often relieve this congestion at once and under periodical observation I have seen many of these cases go on in comfort and without further prostatic enlargement for 10 and 15 years. Periodical health examinations have gone a long way toward drawing the attention of individuals to the great value of these surveys.

If true hypertrophy exists and this cannot always be determined by the presence or absence of residual urine but often only by means of a cystoscopic examination, the prostate should be removed.

An operation once carrying a mortality of 25 per cent has now become—through improved technique, regional anesthesia, proper preparation and post operative care—a procedure carrying a surprisingly low mortality.

A rectal examination showing no enlargement of the prostate does not exclude the possibility of an intravesical hypertrophy, a fibrous prostate or a nerve lesion as a cause for retention. Observation of the interior of the bladder will exclude these possibilities, also a diverticulum of the bladder, a condition frequently overlooked.

Instrumentation in these cases must be carried out with extreme caution and gentleness for traumatism may open up an avenue of infection and the case becomes an operative one at once.

If retention has taken place, catheterization may be difficult or impossible. A suprapubic aspiration partially relieving the back pressure may be preferable and the danger of completely emptying the bladder at one time must be borne in mind.

While these three groups of cases are the ones I wished especially to call your attention to, I would like briefly to mention several other types.

Calculi single or multiple may remain in the kidney, ureter, bladder or prostate for long periods of time, occasionally for years, and give rise to symptoms to insignificant or misleading as to render their presence unsuspected. Seldom however will the urine in such a case be free of microscopic blood and pus cells which when found should always lead to the taking of Roentgenograms of the urinary tract.

While a supply of organisms to the urinary tract is necessary for a urinary infection necessitating the discovery of the primary focus and its elimination, one must bear in mind that disturbed drainage is also an important factor, and that to clear up a urinary infection without a thorough study of the entire tract is often futile. This fact has been recognized in adults and recent investigations of the urinary tract in infants have shown the same to be true. The incidence of congenital anomalies as a cause of impaired drainage is particularly important and many of the urological lesions of adults are also found in children.

An acute urinary infection that does not respond readily to medical treatment, and a chronic infection even in the absence of urinary symptoms, the urine continuing to show microscopic pus and blood cells should have the benefit of a complete urological examination.

In conclusion I wish to emphasize the following. If one waits for definite physical signs and symptoms of urologic pathology, the opportune time for a cure may have passed. Particularly is this true of malignancy, tubercu-

losis and prostatic obstruction. Any symptom or physical sign elicited preferably through periodical health examinations which may suggest a pathological condition of the urinary tract, should lead to a complete urological examination.

Chemical and bacteriological examinations of sterile specimens of urine should be made at regular intervals. With the presence of bacteria, pus or blood cells a catheterized specimen should be obtained in the female. Even in the absence of urinary symptoms the individual

showing pus or blood cells should be under observation, and if the urine does not clear at once, cystoscopic and X-ray investigations should be made.

Few urological lesions are of an emergency nature. They call for painstaking study, often over a period of time. When surgery is indicated a careful consideration of operative procedures, the employment of accurate surgical technique, intelligent post operative care, and continued observation are essential.

## INJURIES TO STENSON'S DUCT\*

By ARTHUR M. DICKINSON, M.D., ALBANY, N. Y.

**L**ACERATION or section of Stenson's duct is not a common condition. During the late war it was seen more frequently because of the relatively high incidence of lacerated wounds of the face. In civilian practice, however, this condition is seen rather infrequently and so, many surgeons assume a rather helpless attitude when confronted with it. As the result of section of the duct, a very distressing condition is created in which the saliva drains out on the cheek. Primary repair of the duct is always worthy of trial and in some instances is followed by very gratifying results. Secondary repair is always much more difficult and the results are not always so satisfactory.

Stenson's duct or the ductus parotideus is about 5 to 6 centimeters in length. At the origin of the duct in the parotid gland the lumen is about the size of a crow quill, at the site of opening into the mouth, the size is considerably reduced. The duct wall is quite dense and moderately thick. The duct arises from numerous branches in the anterior part of the parotid gland. Its course is across and superficial to the Masseter muscle, at the anterior border of which it turns inward sharply and passes into the substance of the Buccinator muscle. It then pierces the Buccinator and runs obliquely forward between the muscle and the oral mucous membrane and opens upon the inner surface of the cheek opposite the second upper molar tooth. While crossing the Masseter muscle, it commonly receives the duct of the Socia Parotiditis which is frequently a separate glandular structure. From this brief review of the anatomical points, it will be seen that the portion of the duct as it lies superficial to the Masseter muscle is more exposed to injury than the portion within the Buccinator muscle. Also it will be quite obvious that injuries to the

Buccinator portion of the duct may be quite simply treated by making a new opening in the oral mucous membrane through which the saliva will drain, whereas injuries to the portion of the duct overlying the Masseter muscle will require more complicated treatment.

Immediate repair of injuries to either portion of the duct is indicated, for if successful repair is not accomplished a salivary fistula, which is very distressing, will result. Salivary fistulae commonly persist until death unless infection of the gland occurs. Infection of the gland may be so severe as to require incision and drainage of the gland. On the other hand, as a sequel to infection, resolution may ensue and be followed by atrophy of the gland, which is a fortunate termination of this condition.

In lacerations of the Masseteric portion of the duct, immediate repair should be tried. Some surgeons claim that attempts at primary repair are never successful, however, results following attempts at primary repair are so satisfactory in some instances, that the attempt is justified in every instance. Immediate repair of the Masseteric portion of the duct demands care and patience. An attempt must be made to suture the severed ends of the duct and to preserve the lumen. The wound must be enlarged sufficiently to enable the operator to see the ends of the duct clearly. This clearness of field can only be secured when all bleeding points are controlled. In enlarging the wound and clamping the bleeding vessels, the branches of the facial nerve are to be carefully avoided. Difficulty is often encountered in locating the distal end of the severed duct, but if a filiform or a small probe is passed up the duct from the oral cavity, its location becomes manifest. The proximal end of the duct can often be located by watching for the site of appearance of the saliva. Having isolated both ends of the duct, these should be carefully sutured together over some object as a guide. Gilette

\* Presented in abstract at Staff Meeting of Memorial Hospital, Albany, N. Y., March 8, 1927.

recommends a small twisted piece of lead which is held in place by sutures coming out on to the cheek. The spiral turns of the lead allow the secretion to find its way along the duct and the ends of the duct are held in apposition by the lead and by suture. He leaves the lead spiral in the duct for about four weeks, during which time the lining membrane of the duct has presumably reformed. He releases the lead by simply cutting the stay sutures which were brought out on the cheek. Other writers recommend various materials as guides. A small piece of catgut extending down from the gland across the site of section but not into the mouth, is reported as having worked well. It absorbs quickly, far too quickly, it would appear, to have much value in holding the ends of the duct in place or in maintaining a lumen until the mucous membrane has bridged the gap and the duct has healed without stricture. Suture of the duct is delicate work and I can heartily commend, for this work, the small needles and holders such as our ophthalmic surgeons use.

Primary repair of fistulae of the buccal portion of the duct may be attempted along similar lines. In these cases results are discouraging and recurrences frequent. Probably the easiest and most satisfactory method of dealing with fistulae of this portion of the duct consists in converting the external fistula into an internal one. The end of the upper segment of the duct is pushed through the mucosa of the mouth, which allows the parotid secretions to drain into the oral cavity instead of on the cheek.

#### REPORT OF CASE

S C M admitted to the Memorial Hospital on July 14, 1926, with a lacerated wound of the left cheek which had been sutured before admission as an emergency measure. The wound was ragged in outline, about two and one-half inches in length, placed obliquely just in front of the parotid gland. The entire side of the cheek was swollen and blood was draining freely from the wound. The injury had occurred about thirty minutes previously when the patient accidentally ran into a projecting angle iron. The sutures were immediately removed from the wound and the wound blocked

off with novocain solution. The wound extended through the Masseter muscle down to the oral mucosa. Several small spurting vessels were secured and tied off. As the field was cleared, several nerve filaments (branches of the facial) and the edge of the parotid gland were observed. The proximal end of the duct was recognized by the collection of a pool of saliva about it. The distal portion was located after a painstaking search of the wound. Attempts at passage of a probe upwards from the oral cavity failed. A silk worm gut suture was then passed up the proximal portion of the duct to the gland and the other end pushed down the distal portion until it emerged in the mouth. With the duct held in place by the contained silk worm gut, its ends were carefully sutured with double O chromic catgut. A small gauze drain was then inserted in the wound down to the duct and the wound closed with fine silk. The silkworm gut was fixed at its point of exit into the mouth, by a suture. After two days the silkworm gut came out into the mouth and had to be removed. The drain in the wound was removed on the fifth day. Ten days after operation there was moderate salivary drainage through an external fistula with some swelling and tenderness of the parotid. Twenty days after operation there was still slight drainage through the external fistula and moderate swelling of the parotid. One month after injury there was no discharge from the fistula and no swelling of the parotid. On the forty-first day after injury, the wound of the cheek was entirely healed, the parotid appeared normal and the patient was discharged from further care. Check up six months later revealed no evidence of the former injury except slight scarring of the face. The patient reported that he had had no trouble of any kind with the face since discharged from treatment.

#### CONCLUSIONS

- 1 Attempts at immediate repair of lacerations of Stenson's duct should always be made.
- 2 Careful suture of the severed ends of the duct should be undertaken if at all possible.
- 3 Surprisingly satisfactory results occasionally follow the attempts.

302 State St. Albany, N. Y.

## NEWS OF THE ANNUAL MEETING

As this Journal goes to press the Annual Meeting of the Medical Society of the State of New York is about to close. The proceedings were conducted with the utmost goodwill and harmony, and a spirit of progressiveness pervaded the entire meeting. The local preparations made by the Committee on Arrangements were most excellent, and all the members and

their wives enjoyed themselves to an unusual degree.

A general account of the sessions and other activities of the meeting will appear in our next issue. The formal minutes of the House of Delegates will be printed as soon as they can be transcribed and verified, probably in the June fifteenth issue.

## PREVENTIVE AND CURATIVE MEDICINE

The object of the practice of medicine is to bring health to every person. The practice fails in its high aim in so far as it fails to make every person healthy.

Who is responsible for the continuance of ill health? Are the doctors responsible? Or are the people themselves?

If the people are largely to blame for ill health, who is responsible for their failure to attain good health? Is poor health and physical disability a crime, as some public health writers assert?

All living things are engaged in an adaptation of their environments, and the greatest struggle of all is that among men. Competition is keen everywhere, and men take supreme pleasure in defying the natural laws of Nature as they imitate the birds of the air and the fish of the sea in an attempt to attain within the span of a single life that adaptation to their surroundings for which lower animals took millions of years of preparation.

Then, too, men are carrying the contest between the mind and the body to the utmost lengths. Feats of endurance consist largely in the dominance of mind over the body until the physical powers reach the breaking point.

Men will never be satisfied with mere health—the essence of modern competition and progress is that of using the vigorous body and mind to the limit of endurance.

When public health orators speak glibly of the displacement of curative medicine by its preventive form, they overlook the tendency of men to use their bodies to the limits of endurance. Men who have achieved success and fame show an increasing rate of mortality because they drive their bodies at high speed long after the warning signs of impending disaster are apparent to the prophetic eye of the doctor. So long as the modern system of competition prevails, just so long will the practice of doctors be predominantly curative.

If the more prosperous class of men will not give heed to the warnings of preventive medicine, what may be expected from those who are not only unable financially to adjust themselves to their environment, but also lack the knowledge of how to maintain health? Instruction and inspirational talks will help the poor and the ignorant to safeguard their health, but they will lag far behind their more favorably situated brethren in the care of their health. Curative medicine will be the most common form of practice among the poor as well as the rich.

The conditions which cause ill health are essentially the same among all classes of people. Worry affects the rich as well as the poor, dancing during late hours is as fatiguing as trundling

a wheelbarrow, and an unbalanced diet is as weakening to the eaters of ice cream as to those who live on potatoes. All men are equals in the sight of their stomachs.

This line of argument does not tend to disparage preventive medicine. On the contrary it opens up an immense new field of practice. It is intended to call attention to the fact that the millennium of perfect health has not yet arrived. Doctors merely have a glimpse of the new field of practice, and that field is so vast that it will never be overcrowded.

Neither is there a sound basis for supposing that the days of curative medicine are numbered. Doctors who have learned the arts of physical diagnosis and the prescribing of medicines will have abundant use for their skill through long lives of usefulness.

The practice of preventive medicine will probably develop along the lines of the recognition of disease at progressively earlier stages until finally the approach of disease will be detected while it is yet afar off and conquerable.

Doctors alone cannot practice preventive medicine—at least not for years to come. The people must have something more than a mere academic desire for health—they must seek it with all their powers.

Preventive medicine must wait on popular education in the elements of hygiene and medicine. People still desire "tonics" to make them strong, and "sedatives" to quiet their excitement. The newly-found prosperity which has come to all classes, the rich and the poor, have found men unprepared to cope with its dangers. Even in infections they are unwilling to forego the pleasures and luxuries of life for a few days in order to avoid spreading their colds and sore throats. Isolations are for the other fellow.

The people have yet to learn the lesson that health cannot be bought, but it must be achieved by self-denial and the active practice of the health virtues.

It is difficult to see how physicians can carry their campaigns of education to much greater lengths than at present. The education must spread from a few laymen who will influence an ever-widening circle of contacts until the desire for health becomes a popular movement that submerges the desire for pleasure and new thrills.

The creation of a new attitude toward health is the work of voluntary health organizations. They are the potent agents which will be the efficient allies of the medical profession in leading the people to the Promised Land of Health.

## MEDICINE IN THE DAILY PRESS

The reader of a daily paper can find information on almost any subject. The newspaper is not a medical journal and yet it contains so much medical news that one successful practitioner of medicine said that he did not take a medical journal because he got his medical information from the *New York Sun*.

The medical news contained in the leading newspapers is surprisingly accurate as to facts. If it is wrong, the fault lies with the physicians who supply the news rather than with the reporters and editors. The newspapers are also wise in their editorial comments on current medical news and in the instruction which they give to the public. The subjects of which they treat have the added advantage of being those chosen by experts in the art of interesting the people. If the daily paper of a large

city carries medical news and editorials, one may be sure the items have a human interest to the public.

The newspapers also note the anniversaries of leading medical events, such, for example, as the editorial in the *New York Herald-Tribune* of April 20, entitled "A well-remembered leg," in which is recalled the boy whose compound fracture of his leg on August 12, 1865, received the first antiseptic treatment given by Joseph Lister, with complete prevention of the supperation which had always accompanied such wounds. Where else than in a daily paper would one be likely to find such information?

The Daily Press department of this Journal is a concrete demonstration of the high standard of medical news in the current newspapers.

---

## CONFLICTING TESTIMONY

The legal department of this issue, page 560, contains a description of a lawsuit in which three stories are told. The first is the story of the patient who claimed that the doctor was negligent when he performed a serious operation on her. The second story is that of the doctor who said he had applied ichthyol to her cervix at an office call, and had later visited her twice in her house for mild pleurisy.

The third story was that of a physician who had examined her six months later and got a history that she had been in a hospital for a miscarriage and posterior pelvic abscess, of which corroborative signs remained in the pelvis. When the case came to trial, the patient failed to appear.

Accurate records constitute the best kind of insurance against malpractice suits.

---

## LOOKING BACKWARD

*The New York State Cancer Laboratory* — This Journal for May, 1907, contains a paper by Dr. Roswell Park, Director of the State Cancer Laboratory, in which he referred to the impatience of legislators who expected an immediate solution of the problem of the cause and cure of cancer, and wrote —

"The ever-present question with us is one of self-existence. It may be perhaps thus put: Does the work accomplished justify our continuance until it has been in some measure accomplished? There can be no doubt that if any unprejudiced person will visit the institution and acquaint himself with what is doing and has been done he will leave it feeling that it is one of which New York State may well be proud, and that it is deserving of the heartiest public support. Some of our legislators unacquainted with its purposes and the character of its work have come in hostile spirit ready to condemn. In every instance, however, they have gone away enthusiastic supporters and have ever since been our best friends.

"For my own part, if I may close this report

with a personal sentiment, I cannot help feeling that we are today much nearer the secret so long sought than we were eight years ago. In fact, I feel that the past eight years have taught us more than the previous eight decades, and that much of what has been thus revealed has come from the little institution in western New York, which has been supported by the State, urged thereto by the importunity of a few friends of science and progress who have had sufficient influence to secure the amounts appropriated, though each year with difficulty and after long-winded explanations and personal solicitations. This should not be necessary were there a sufficiently and reasonably wide comprehension of the difficulties attaching to such scientific research. For myself, the most important question is settled, although it is not yet in such shape that it can be briefly stated or widely taught, nor perhaps can we expect it to receive the prompt and unanimous acceptance of a profession which is always slow to accept even revealed truth."

# MEDICAL PROGRESS

**Encephalitis Complicating Measles**—The increased tendency to encephalitis at the present time has been made manifest by much cumulative testimony. This lesion was recognized as a sequela in the recent pandemic of influenza and at a still earlier period Economo isolated the disease known as legarthic encephalitis. An association, which is largely experimental, has been recognized between the diseases herpes and varicella and encephalitis, and last year the development of postvaccinal encephalitis led to the recollection that the latter occasionally follows or complicates variola. It is even claimed that the meningoencephalitis of metasyphilis appeared only within comparatively recent years as a result of certain unknown factors which make the human brain less resistant to infection. Hence it need not surprise us to read an account in the *Muenchener medizinische Wochenschrift*, January 21, 1927, by F. Lust of four cases of encephalitis complicating measles, which was not especially prevalent and not of severe type. This complication is not entirely unknown for it is mentioned in old as well as comparatively recent textbooks, sometimes with descriptive cases. It has always been a very rare complication yet here is one practitioner who saw four cases during the past year. There was a marked absence of type and the picture varied from typical encephalitis lethargica to narcolepsy. The author is not the first recent writer to enter this field for he was preceded by Mosse and Brock. Despite the high natural mortality of encephalitis the author's patients all recovered. In addition to simple encephalitis cases have been described of exclusive myelitis and polioencephalomyelitis.

**Ligation of the Jugular Veins in Septic Angina**—R. Stahl of Professor Curschmann's medical clinic at Rostock refers to the apparent role of peritonsillar thrombophlebitis in the production of fatal postanginal sepsis. In theory ligation of the jugular of the affected (thrombosed) side might save life. Professor Lenhartz has recently reported a series of fatalities in which operation was not performed in time to rescue the patient. No similar case could be found in the Rostock records, but singularly enough one presented itself during the research. The patient, a man of 33, had a quincy of the right tonsil in which the abscess opened spontaneously after this the lesion developed in the opposite side. There were evidences of beginning sepsis although nothing to suggest thrombophlebitis on either side. It

was recalled by a consultant that the latter lesion could run a silent course, and at his suggestion the jugular vein of the left side was tied after operation had shown that a thrombus had actually formed. It was evident, however, that the thrombus was not isolated and it doubtless extended into the subclavian vein. The patient survived the operation some days but succumbed finally with evidences of septicopyemia. Thus far at least twenty cases have been treated in this manner without saving life—the fatal ending presumably being due in part to the fact that metastases had antedated the operation. The sole way in which thrombosis can be recognized clinically is by the superintention of rigors—a pathognomonic sign. That life can be saved occasionally by the operation is shown by the favorable cases of four reporters although the high mortality indicates that success is problematical.—*Deutsche medizinische Wochenschrift*, January 28, 1927.

**The Indiscriminate Use of Iodine a Menace to Goiter Patients**—Israel Bram, writing in *American Medicine*, February, 1927, quotes from a number of authors who protest against the indiscriminate use of iodine and iodized products for the prevention and treatment of goiter. He states that though minute doses of iodine might be found useful in the prevention of goiters in the so-called "goiter belts," the enforced administration of this drug through legislative enactments, and even through so-called educational health movements, is productive of more harm than good. While a percentage of goiter cases present in so-called belts is probably due to iodine deficiency, there are many, if not more instances of goiter in those regions due to other causes, among which are the physiological changes incident to adolescence, pregnancy, lactation, menopause, the infections, and heredity. The administration of iodine cannot assist these patients to health. Iodine probably improves exophthalmic goiter temporarily, but Bram has seen some instances in which the administration of iodine in exophthalmic goiter has resulted in "tremendous enlargement of the thyroid gland to such an extent as to produce almost fatal asphyxia from pressure, and the remaining symptoms of the disease were brought to such a high peak of crisis as to render it almost impossible to bring the patient back to a degree of safety." When surgeons admit, as many of them now do, that they do not succeed in curing exophthalmic goiter through thyroidectomy, and many other keen and open-minded clinicians condemn the application of the knife in this not local, but constitutional

condition, it is time that everyone should awaken to the realization of cold facts. The time has come, Bram says, when indiscriminate thyroid surgery and the fad of iodine administration in all cases must cease.

**Diathermy in Hypertrichosis**—P. J. Van Putte, a dermatologist of Utrecht, mentions the unsatisfactory character of the usual treatment of facial hypertrichosis, for the patients demand that the hair papillæ be destroyed yet without visible scarring, while they object to the pain of ordinary electrolytic epilation. It was once thought that rontgen epilation would answer the various requirements of the patient, but the dose required to destroy the hair papillæ is too great and the method is now restricted to epilation in connection with the treatment of favus and parasitic sycosis. Quite recently diathermy coagulation has come to the front and there is seen to be an immense economic advantage in this method over electrolysis, for in the latter there is necessary an exposure of 40 to 60 seconds with an intensity of 2 milliamperes, while in diathermy, with an amperage 150 times as great, the duration required is but 1-10 second, and even less. Diathermy has been used with widely differing technique, by Lanzi of Italy, Bordier of Lyon, Rosenstein of New York, and Kats and others besides the author in Holland. Thus Lanzi requires a contact of but 1-200 second while Bordier uses an intensity of but 20 to 50 milliamperes with an exposure of a few tenths of a second, and Rosenstein 80 milliamperes with an exposure of 10 to 20 seconds. The contacts are made with needles and their holders, as in electrolytic epilation, with various provisions for insulation. The author says he gets the best results with 40 to 50 milliamperes and about one second of contact for hairs of medium thickness.—*Nederlandsch Tijdschrift voor Geneeskunde*, February 19, 1927.

**Treatment of Eclampsia in General Practice**—Cellan Jones advises that with the onset of premonitory symptoms of eclampsia the patient should be confined to bed, and three ounces of compound senna mixture, with one dram of magnesium sulphate to each ounce, should be given every eight hours. No food is allowed, but water or weak tea is permissible. Large fluid consumption must be continued until forty ounces of urine have been passed on two consecutive days. Then if all is well, milk may be given, leading to other light diet. In the more severe cases, especially those beginning after labor has been terminated, morphine is given in sufficient doses to keep the patient narcotized. Magnesium sulphate, by its synergistic action, enhances the sedative effect of the comparatively small doses of morphine. Luminal has replaced chloral hydrate, for the reason that it is not a cardiac

depressant like chloral, and in addition has a specific dilating effect on the vessels of the brain. Although, generally speaking, Jones does not believe in venesection, he recommends it in practically every case in which the blood pressure exceeds 140 mm of mercury, and even this stipulation may be disregarded when the rectal temperature is high and convulsions frequent. The use of pituitrin in eclampsia he regards as most dangerous. When labor complicates eclampsia, if the cervix is not dilated, manual dilatation should never be employed, and version is contraindicated unless delivery is impossible without it. Forceps may be resorted to only to shorten the second stage, when the cervix is fully dilated and the presenting part almost on the perineum. The treatment adopted for the eclamptic state must be that which is least exhausting to a comatose patient with rapidly recurring and dangerous convulsions.—*British Medical Journal*, February 19, 1927, 3450.

**Tender Spots on the Chest Wall in Angina Pectoris**—Morris H. Kahn calls attention to the hyperesthesia of areas on the chest wall which is commonly found in association with anginal pain. It is referable to the impaired nutrition of the heart wall and the sensitiveness of the aorta and coronary artery area. It is often complained of by the patient and can be definitely localized objectively. Of 55 patients with angina pectoris, studied by the author, 48 presented tender spots along the ribs or on pressure over the sternum. This sign was also present in nonanginal cases of aortic or myocardial disease, but in individuals without heart involvement, tender spots on the chest were never found. In angina pectoris, the tender spots are most often located on the second, third, and fourth ribs to the left of the sternum (fourth cervical and second and third thoracic) and over the second and third ribs in the outer part of the right pectoral region (fourth cervical). The tender spots on the chest wall persist for a long time after an attack of angina pectoris and sometimes continue throughout the intervals between the attacks. They are especially valuable in the differential diagnosis between myocardial lesions and affections of the upper abdominal viscera. In eliciting the sign, uniform pressure is used by means of the thumb or tip of the finger over the sternum and ribs on each side. The periosteum of the ribs seems to show greater sensitiveness to pressure than the skin and seems to respond through the corresponding spinal segment to a much lower stimulus. When the points are found they can be recorded by a circle painted with tincture of iodine and a photograph of the chest then made for future use.—*American Journal of the Medical Sciences*, March, 1927, clxxiii, 3.

**Treatment of Friedreich's Paramyoclonus Multiplex**—John Reid (*Practitioner*, March, 1927, cxviii, 3) states that Friedreich's myoclonus, which is a sudden, fast, snap-like clonic contraction of a muscle, a portion of a muscle, or a group of muscles, usually occurs in adults—males frequently. It is closely related to hysteria, chorea, convulsions, tic, and neurasthenia. The condition does not respond to medical treatment. As the attacks may be initiated by pressure over one ovary or testicle, the assumption is that paramyoclonus is due to a disordered state of the internal secretion of the gland in question. The treatment therefore resolves itself into ovariectomy complete on one side and partial on the other, or unilateral vasectomy in the male. The author cites the case of a woman, aged 56, who had had the disease for eighteen years and was cured by ovariectomy, a small portion of one ovary being left. In this case there were a few days of great depression, almost amounting to melancholia, followed by a few days of great exhilaration of mind, going on regularly over a long period. As the mental condition cleared up after a few months, it showed clearly that there were no real organic brain lesions. It therefore seems that operative treatment is surely justified. In a second case the author later performed a Lockhart-Mummery operation for bad rectal prolapse, with magnificent results. The shock and prolonged careful after-treatment required did not cause any recurrence of the spasms.

**The Nervous Complications of Varicella, Variola, and Vaccinia**—E Glanzmann of Berne has written a timely monographic article on this subject which would be too extensive for a short abstract were it not for the fact that the author thoughtfully tabulates all of his results in a small compass. Varicella has been followed by meningitis, myelitis, ataxia, tremor, hemiplegia, and chorea. However the entire number of these cases on record is below twenty, so considering the frequency of chickenpox they may be regarded as curiosities. Variola has been followed in a few instances by myelitis and paraplegia and by an association of aphasia and ataxia. Some of these observations are quite antiquated. Under vaccinia the author lists encephalitis, meningitis, and encephalomyelitis. These all appear to be of recent occurrence and show something like type, for the complications tend to develop around the eleventh or twelfth day after vaccination, although the limits are the fourth to the fifteenth day. We do not know whether all the known cases are included. Bastiaanse of Holland has one group of 35 cases while seven have been reported in England since 1914. Luksch reported four and Leimer three cases, while other scattering observations bring the total up to fifty-four. The author concludes that all three

diseases can cause very similar nervous complications under unknown and extremely rare conditions. This similarity, he thinks, confirms his belief that the three are basically related. He has sometimes practised repeated vaccination in children with chickenpox but no case ever took. This immunity, however, is very short lived—*Schweizerische medizinische Wochenschrift*, February 12, 1927.

**Comparison of Functional Tests of the Liver**—W Lowenberg with others from Professor Kuttner's clinic at the Rudolf-Virchow Hospital give the results of their comparative study of tests of the functional efficiency of the liver in the following summary. In catarrhal as well as in syphilitic jaundice it is possible to show with unanimity that the parenchyma is damaged and henceforth we must speak not of catarrhal jaundice but of a form of hepatitis. In hepatic cirrhosis overloading with galactose will show a functional disturbance while studies of the duodenal content and elimination of coloring matters are mostly unsatisfactory. On the other hand in syphilitic hepatitis the galactose test is a failure while a slight degree of urobilinocholia reveals disturbed hepatic metabolism. In uncomplicated cholecystitis and cholelithiasis none of the tests showed injury to the parenchyma although the appearance in the blood serum of quinine-resistant lipases in these patients may indicate mild injury. But cholangitides, in contradistinction to the conditions just mentioned, are often accompanied by functional insufficiency and in addition pathological organisms are found in the duodenum. In uncomplicated closure of the common duct there is no disturbance of function. In pernicious anemia there is no invariable insufficiency although there are frequently anomalies in the excretion of coloring matters. In practical importance the authors rank first the Ehrlich aldehyde reaction in the urine as indicative of slight degree of hepatic lesion. Next they enumerate the galactose test. Tabulations show that the regulation procedures comprise tests of the duodenal content, blood serum, and urine, chiefly for coloring matters and blood sugar, also the duodenal bacteriological flora. On the whole the authors regard these tests as of the greatest clinical significance.—*Klinische Wochenschrift*, March 5, 1927.

**Popular Urticaria**—Rupert Hallam, writing in the *British Journal of Dermatology and Syphilis*, March, 1927, xxxix, 3, presents a study of the etiology of this peculiar disease of childhood, concerning which comparatively little information has appeared in the literature. The skin lesions resemble the bite of a flea or gnat, but the characteristic central hemorrhagic puncture is absent. In a series of 52 cases of popular urticaria, it was observed that when children

were admitted to the hospital the condition rapidly cleared up. All of these children after recovery gave positive reactions to one or more protein extracts. As causative agents the bite of the flea, the louse, and the bedbug were excluded. Likewise neither the *ovuris vermicularis*, the cockroach, the cricket, nor the proteins of domestic animals could be incriminated. Sensitization to mother's milk or other food proteins could not be definitely demonstrated, nor could the affection be attributed to proteins from a focus in the body of the patients, inasmuch as the rash disappeared when the children were placed in the hospital. The tests appeared to indicate the presence of a hypersensitiveness to protein, but did not afford a specific diagnosis. The author concludes that there is a primary undiscovered cause of papular urticaria and that there is some justification for believing that it is caused by protein sensitization, though the specific protein has not been determined.

**Attempted Use of Living Saprophyte Cultures in Medicine**—F. Weissenfeld refers to a new product of the serum factories which is now made under a proprietary name and which consists of living cultures of saprophytic organisms which are thrown into the veins with the object of setting up an artificial fever. The idea is a direct outgrowth of the use of malarial blood and plasmodium cultures in metasyphilis and of cultures of the spirochete of recurrent fever in the same condition. The first question to ask relates to the possibility of serious damage, the second of course has to do with the question of efficacy. The author tested the cultures on paresis and on parkinsonism following lethargic encephalitis, and relates four cases. Fever was not always produced but in two of the patients it went as high as 104° F. The author sums up as follows: the first subject with paresis tolerated the remedy well, but the therapeutic result was negative which was not surprising in view of the fact that the case was far advanced. The second paresis victim failed to react with fever after a number of injections. In the two cases of post-encephalitic disease there was a reaction in the joints, expressed in one merely by pain in one hip, and in the other a severe arthritis of a shoulder joint, while the mental state in the latter patient was aggravated.—*Deutsche medizinische Wochenschrift*, February 18, 1927

**Autopyotherapy**—A. Levinson of Moscow refers to articles of recent years devoted to this subject by Mokai (1923) and Barfurth (1926). He is silent on earlier efforts in this direction which go back at least 15 years, including the uses of pus by veterinarians. The method which he has practised may differ from its predecessors—most of them at least—through the fact the pus

is injected in all of its natural virulence, so that we may speak of autoinoculation (*Muenchener medizinische Wochenschrift*, February 11, 1927). One would under such circumstances anticipate the development of abscesses at the inoculation site but the author does not desire such a result which he looks on as untoward, and in general abscess does not result and even when it does it may not discharge or require opening. The author reports briefly a number of cases in some of which the results were quite negative—thus a cold abscess was not benefited while in certain cases of purulent meningitis the infected liquor when injected was inefficacious. Among cases which appeared to yield to treatment were one of meningococcus meningitis in a baby, a purulent meningitis of unknown nature in a six-year-old boy, an abscess of the lung (post-pneumonic) in a baby, and an intermuscular abscess in a boy of 12 years. In the latter the pus from a secondary inoculation abscess was again inoculated. The author regards his results as sufficiently encouraging to go ahead with the treatment. He has no theory as to how such cases are favorably affected.

**Albumin-Free and Salt-Free Diet in Fever**—S. Ederer and E. Kramar call attention to the increased breaking down of albumin in fever and the inability of the fevered organism to assimilate albumin. Hence it is an error to try to make good this deficit and the rational course is to eliminate protein from the diet. In fever there is an increased requirement of water with a diminished giving off of the same. Both albumin and salt play a role in the water economy of the body and both these substances increase the water requirement in fever. We know that in the nursing these two substances can also produce fever. Salt requires a certain amount of water for its osmotic activity which is subtracted from that of the body requirement. In fever as in all other states the calory requirement must be maintained and after a year's experiment the authors announce the following as an ideal fever diet, though apparently they are chiefly interested in the first two years of life where the action of albumin and salt in the production of fever is obvious. For the nursing they prescribe doubly centrifuged cream containing 15 per cent sugar in solution (equal parts cane sugar and dextrinized sugar) the cream is then further diluted with twenty parts of the solution. For older children the dilution is but 10 fold and cocoa is added. The nursing takes 100 mgm for each kilo of body weight. The ratio of fat-carbohydrate-protein is 3-15-0.1, so that protein is almost absent. On this diet the fever abates.—*Deutsche medizinische Wochenschrift*, March 18, 1927

# LEGAL

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York.

## PHYSICIANS' HAZARDS IN A LUNACY COMMITMENT

On a farm several miles from a small village, there lived a farmer and his wife, to whom there were born a number of children who were raised upon this farm. As the children reached their adult years they moved into the adjacent village, some of them entering business, marrying and having families of their own and becoming prosperous respected citizens of the community. After the death of the father two of the daughters continued to care for the mother. They, too, eventually left the farm and moved with their mother to the adjacent village. These two daughters never married and continued, until the mother's death at a ripe old age, to attend and care for her.

The younger of the two daughters when well advanced in womanhood began to show and gave evidences of mental abnormalities and by reason of the close association of the two sisters the elder one likewise became mentally affected.

For a period of years their actions by neighbors and people of the village were denominated as queer. However, their mental conditions became progressively worse, so that neighbors and townspeople complained to the village authorities of the conduct and actions of the sisters because of their fear for their personal safety. The other members of the family of these sisters were naturally reluctant to take steps for the institutional care of the mentally afflicted women. The townspeople, however, bore the condition for a period of years until the situation became so acute that pressure was brought to bear upon the village authorities and the Overseer of the poor, in accordance with the authority vested in him by statute, petitioned for the commitment of the sisters as insane persons needing institutional care and treatment. After the making of the petition by the Overseer of the poor, likewise in conformity with the statute, a joint mental examination was made by two physicians examiners in lunacy. These physicians were respected citizens of the community and had honorably carried on the practice of their profession for a great number of years. They had both observed the sisters for a long time and were familiar with their irrational actions and with their threats to neighbors and people of the village and of the disturbances which they had caused in the community.

After the making of their mental examination and the signing of their certificate of lunacy, the sisters were taken into custodian care in a state hospital for the insane and an order was made by the Justice of the Peace committing them to such hospital.

Neighbors had continuously complained that they were in fear of these sisters by reason of their threats. In one instance, to throw vitriol upon an old lady whom they constantly assailed with abusive terms, and in another instance of threatening to chase a bull-dog after a person who happened to stop on the road in front of their house and charging that the reason he stopped was to kill their mother and attack her and her sister. At another time when a person had called at their home with reference to the establishment of a local fire department they chased this person away and one sister called to the other to go get a gun. At another time when a resident minister was about to be married, one of the sisters caused a disturbance by charging that the minister could not marry his prospective wife as he had been engaged to her and had broken the engagement.

After the sisters had been taken to the state hospital they remained patients therein for almost ten years and were finally released by a Justice of the Supreme Court under a writ of habeas corpus which had been procured in their behalf by a former attendant in the hospital. At the time of their release and on the examination before the Justice on the writ of habeas corpus, it was the opinion of the physicians at the hospital that these sisters were not cured of their mental ailment and should continue to receive institutional care. During all of the time that they were patients in the hospital their condition of mental derangement failed to improve and they almost never cooperated with the physicians or attendants at the hospital, continuously refusing to do the things that they were requested to do or to attempt to reply to the inquiries of the physicians made on numerous examinations. At all times while they were patients at the hospital they claimed that they were improperly held in custodial care. They failed to cooperate towards the relief of their condition so as to provide for their release or take other steps to determine their sanity, with one ex-

ception After about eighteen months in the hospital a writ of habeas corpus was procured in their behalf Upon the return of the writ they appeared before a Justice of the Supreme Court who, after observing the sisters and hearing one of them attempt to testify, appointed a physician of his own selection to visit the hospital and make a mental examination of these patients This physician, after his examination, rendered his report to the court finding that the patients were paranoias, that they had fixed delusions and hallucinations and in his opinion should be kept in detention, not only for their own good, but also as a protection for the community After the rendition of the report of this physician the attorney who represented these patients in the procural of this writ of habeas corpus withdrew the same and consented to its dismissal

Thus, up to this point we have the opinion of the neighbors and people in the community, the judgment of the Overseer of the poor who made the petition, the Justice of the Peace who signed the commitment, the authorities at the hospital, the opinion of the physician appointed by the court at the time of the procural of the first writ of habeas corpus and of the attorney who represented the patients at that time

Until the application for the second writ of habeas corpus procured by these patients, almost ten years after their original commitment, no judicial steps were taken by them to have their mental conditions inquired into by any court or physicians appointed by the court in an attempt to procure their release and discharge from the hospital However, during this period they continuously wrote letters to various city, county and state officials complaining of their detention in the hospital and of the hospital authorities During the first thirty days after their commitment to the hospital these patients had a right to appeal from the order of commitment, also during all their stay in the hospital they had a right to have the question of their insanity determined by a writ of habeas corpus and there is no limitation on the number of times that they could apply for writs of habeas corpus Likewise during their entire stay they had a right to procure, if the same were justified, a certificate from the superintendent of the hospital certifying that they had recovered from their ailment and it was safe to permit them to be at large without possible injury or danger to themselves or others. They had a right, if the facts justified, to have their case determined in their favor by the State Insanity Commission Nevertheless, from the time of the application for the first writ of habeas corpus until the time of the application for the second writ of habeas corpus, a period of about seven and a half years, they availed themselves of none of these rights and

continued under the supervision and jurisdiction of the hospital as patients of the same

At the time of their release from the hospital the orders of release provided that they be in the custody of the person who petitioned for their release (a former attendant of the hospital where they had been patients) and in the case of one of the patient's a provision was made that she should not return to the village of which she had formerly been an inhabitant

About nine months after the discharge from the hospital these patients instituted actions against the two physicians who had made the original certificate of mental examination, demanding damages in a large sum of money With the commencement of these suits there ensued one of the longest drawn out legal battles in which any physicians had ever been engaged

On behalf of the defendants, attacks were made on the original complaints requiring the plaintiffs to separately state and number the causes of action which were contained therein, as the original complaints attempted to set forth at least three causes of action, (1) charging the defendants with assault, rendering them unconscious and removing them by force to the state hospital while so unconscious and without their knowledge, (2) for a conspiracy to get rid of them by forcibly taking them from their home and locking them up in a hospital for the insane, and (3) for a wrong growing out of and based upon claimed false testimony of one of the defendants at the time of the return of the second writ of habeas corpus After argument before the court this motion was granted and the plaintiffs then served amended complaints Attack was likewise made upon these complaints and a motion made to compel the plaintiffs to strike out from the complaints allegations which were irrelevant and immaterial and which if they had been permitted to remain in the complaints would have reacted to the detriment of and would have been prejudicial to these defendants at the time of trial This motion was likewise, after argument before the court granted and the plaintiffs were compelled to serve second amended complaints The answer of the defendants was served to the second amended complaints

When the cases were finally placed upon the calendar for trial, about a year after its institution, because of the crowded conditions of the calendar, the cases did not come on for trial the first time until almost two years thereafter A jury was empanelled and the plaintiffs made their opening statement to the court and jury Upon the making of this statement, on behalf of the defendants, a motion was made to dismiss the complaints on the ground that the actions were barred by the statute of lim-

itations, in that the wrong for which they were suing had been committed more than ten years prior to the commencement of the actions and that the wrong was an action for false imprisonment, which was barred by the two years statute of limitations. The trial court agreed with the argument of the defendants and dismissed the complaints. An appeal was then taken on behalf of the plaintiffs from this order of dismissal and the Appellate tribunal by a divided court reversed the judgment of dismissal and ordered a new trial.

In November of the following year, or almost four years after the commencement of the actions, the cases came on for the second trial. This trial lasted four days. At the conclusion of the trial and after about four hours' deliberation by the jury, a verdict of \$10,000 was rendered in favor of each of the plaintiffs. Upon the rendition of the verdict, a motion was made on behalf of the defendants to set aside these verdicts, which motion was granted.

In preparation for the trial of these cases a voluminous case book and hospital record of the plaintiffs had to be examined and analyzed. Numerous witnesses, residents of the community had been interviewed and their statements procured. Arrangements had to be made for the appearance of these persons as witnesses upon the trial. The trial of these actions was held in a county somewhat distant from that in which the plaintiffs had originally resided. Physicians who during the stay of the plaintiffs in the hospital were attendants therein, had left that particular hospital and were scattered in various parts of the state and also outside of the state, and many of them were brought hundreds of miles to testify in behalf of the defendants as to their observation and treatment of the plaintiffs while patients in the hospital. A large number of witnesses, residents of the village in which the plaintiffs had lived, had to be daily transported by bus from their place of residence to the court.

About six months later the cases came on for the third trial. At this time the trial lasted five days and at its conclusion the jury disagreed. The various persons who had been witnesses at the preceding trial were likewise witnesses at this trial and had to be brought from great distances to the place of trial. The plaintiffs were not discouraged and were still pressing this litigation and even this third trial did not conclude the cases, for five months thereafter the cases came on for trial for the fourth time. After a five-day trial the jury, after an impassioned plea by their attorney to give them vindication and to render a verdict in their favor, if it was only for one dollar, found in favor of the plaintiffs for the sum asked for by their attorney, to wit, one dollar.

At this point one would suppose this long drawn out legal battle had reached its final termination. Such, however, was not the case. Fifty-nine days after the rendition of the one dollar verdict in favor of the plaintiffs, the presiding Justice set the verdicts aside. Here then after four trials it seemed that all the work done in behalf of the defendants—elderly physicians—might be in vain. These four trials had been a tremendous tax upon everyone. The preparation alone represented a herculean task. It was a great tax upon these elderly physicians, only one of whom was able to attend the trial. It was a tax upon the counsel, it was a tax upon the witnesses, it was a tax upon the court and juries, giving as it did fifteen days to the consideration of these cases.

The question now arose as to what course to follow. It was decided to take an appeal from the order of the trial judge setting aside the one dollar verdicts. In the preparation of the record on appeal a stenographic transcript of the testimony of the witnesses had to be procured and a printed record, consisting of the pleadings in the case and the testimony of all the witnesses, the summation of counsel to the juries, the charge of the court to the jury had to be prepared and printed, making a printed volume of over seven hundred pages. In support of the argument on behalf of the defendants an analysis of the record on appeal was made and a printed brief prepared in their behalf. About fifteen months after the one dollar verdicts had been set aside, the cases were argued before the Appellate Court and after deliberation by that court, by an unanimous decision, it reversed the order setting aside the verdicts and reinstated the same. The learned Appellate Court decided that irrespective of any possible irregularity in the certificate of lunacy the plaintiffs were in fact insane and subjects for custodial care in a state institution for the mentally afflicted. That they had, therefore, suffered only nominal damages and that the one dollar verdicts should stand.

The time has now expired when an application could be made on behalf of the plaintiffs to appeal to the Court of Appeals from the decision of the Appellate Division and therefore, the last chapter in this long, tiring and difficult litigation has been written.

No case more eloquently illustrates the difficulties and the hazards of the practice of medicine. No case shows more clearly for how long a time members of the medical profession may be forced to continue to defend the procedures they have followed. When the cases came on for trial the Overseer of the poor who made the petition, the Justice of the Peace who had signed the order of commitment and many

other witnesses, residents of the village in which the plaintiffs had resided, who for years had known and observed the patients, had died. These things, in addition to the inherent difficulties of the cases added greatly to the burdens of the defense. Had any substantial verdict been secured against these physicians it might have been such as to dissipate their

earnings of a lifetime. Fortunately, this did not happen.

These cases which like that of *Jarndyce vs Jarndyce* in Dickens' "Bleak House," gave every evidence of going on and on without any termination, have now been brought to a final and happy conclusion.

### CLAIMED NEGLIGENCE IN OPERATION RESULTING IN BLOOD POISONING AND PLEURISY

The patient in her complaint charged that believing she was suffering from an intestinal disorder, she consulted the defendant with reference to the treatment of her condition. That on the 19th of January, as such physician he undertook to perform an operation upon her, which was negligently and carelessly done, thereafter she suffered from the effects of blood poisoning. It was charged that the defendant in the performance of his operation used unsanitary, improper and inadequate instruments. It was further charged that the defendant physician, when the plaintiff began to suffer from the effects of the blood poisoning wrongfully diagnosed the patient's condition and treated her as if she were suffering from appendicitis and that he had made a wrong diagnosis in that she was not suffering from appendicitis, but from blood poisoning. That by reason of the defendant's improper treatment the patient developed pleurisy and on the 6th day of February it was necessary for her to enter a hospital where she underwent an operation for the blood poisoning and pleurisy. That she remained at said hospital until the 9th day of March. That while in the hospital the plaintiff's condition was properly diagnosed as blood poisoning and pleurisy and that the operation performed upon her was done to offset the defendant's negligence and carelessness. That by reason of the defendant's negligence and carelessness, she suffered bodily and mental injuries, she became greatly debilitated and remained such for a long period of time, that her general health had become so impaired that she had lost the ability to bear children.

This patient had called on the defendant in January complaining of stomach trouble and pains in the back. Upon examination the physician found that she was suffering from an inflammatory condition of the cervix. At that time he treated the infected area with an application of ichthyol and inserted a piece of cotton saturated with ichthyol. On the following day the patient returned and the cotton was removed. Nothing was heard from the patient for several days, when the

physician was summoned to the patient's house. Upon examination he found the patient suffering from pleurisy, at which time he properly prescribed for her condition. When he called again on the patient two days later he found her condition improved and instructed her to continue taking the medicines that he had previously prescribed.

The physician denies that he had advised the patient that she had appendicitis or that he had ever operated upon her, and claims that the only treatment he had ever given her and the only medicaments which he had used were those as previously stated.

About six months after the patient had been attended by the defendant a physical examination was made of her. At this time she gave a history that upon entry at the hospital a diagnosis was made of an abscess behind the uterus, and she had a spontaneous miscarriage at three months while in the hospital. The plaintiff told the examining physician that she had gone to the defendant doctor for a supposed pregnancy as she had not had a period for six weeks. That he had examined her and used some instruments. That she had been in bed ever since and was still under the doctor's care. That she had no chills or fever, but feels weak and does no work, that she was treated by the defendant doctor four or five times at home and she then went to the hospital where she remained for six weeks and since then has been home in bed. The examining physician upon his examination found the patient looking very well and showing no evidence of what she claims to have gone through, except some slight thickening in the posterior sac of the vagina where the doctor who operated upon her claimed that he opened an abscess. The examining physician further found that the patient's condition at the time of examination was so good that she need not be in bed and should be up and doing her usual work, that she was neither anemic nor septic and exaggerates her present disability. When the action came on for trial the plaintiff failed to prosecute the same and a dismissal was had.

# NEWS NOTES

## FEEBLE MINDEDNESS

The National Committee on Mental Hygiene issued a pamphlet in which misconceptions regarding insanity were printed in parallel columns beside the modern ideas of physicians on those subjects. This was reprinted on page 1006 of the December 1926 issue of this JOURNAL.

The National Committee has recently published a similar pamphlet regarding feeble-mindedness, or mental deficiency, as it is more properly called. The following ten misconceptions are listed, and after each one the modern attitude of the medical profession is given.

1 "That feeble-mindedness is a mental disease."

"Feeble-mindedness is an arrest of intellectual growth in the early development life of the individual."

2 "That feeble-mindedness can be cured like mental disease."

"True feeble-mindedness is an organic condition involving a lack of development of brain tissue and cannot be cured in a medical sense."

3 "That feeble-mindedness is always hereditary."

"Many of the feeble-minded, estimated as approximately half, owe their mental defect to accidental causes, such as pre-natal neglect, injuries at birth, and early childhood diseases like scarlet fever, infantile paralysis and 'sleeping sickness'."

4 "That sterilization is the best solution of the problem of the feeble-minded."

"Sterilization will not solve the problem because feeble-mindedness is not always due to a defective germ plasm, and because in our present state of knowledge about the laws of heredity we cannot say how much or when feeble-mindedness is transmissible."

5 "That the feeble-minded are all a menace to society."

"The feeble-minded are not necessarily delin-

quent or criminally-minded *per se*, and that their occasional danger to society depends upon other factors besides their mental defect. There are good feeble-minded as well as bad feeble-minded."

6 "That segregation in institutions is the only way to control the feeble-minded."

"Segregation is necessary only for the low grades of feeble-minded and for the relatively few defective delinquents, or the incorrigibly bad feeble-minded, for whom little can be done in school or at home."

7 "That the feeble-minded are a total loss to society."

"Most of the feeble-minded, if taken early, can be trained to do productive manual work, and with understanding, guidance, and supervision can lead happy, useful, and social lives."

8 "That the feeble-minded are not teachable at school."

"Their intellectual capacities are too limited to profit from the ordinary school curriculum, but they can be taught a trade in the special classes which are being provided in increasing numbers in the public schools."

9 "That the feeble-minded are all equally mentally defective."

"There is a gradual curve from the extreme condition of the idiot, whose mental age is one or two years, to the moron and borderline cases, in which the mental age ranges from eight years to normal."

10 "That the feeble-minded are readily recognizable."

"The diagnosis of feeble-mindedness is frequently a difficult matter, even when the intelligence test is administered by an expert psychologist, and that the psychiatrist must often be called in to eliminate various causes of remedial mental backwardness before a condition of true mental defect is established."

## THE GENEVA ACADEMY OF MEDICINE

The physicians of Geneva have organized an Academy of Medicine with fifty-seven charter members. The booklet of the Academy states:

"At the April, 1925, meeting of the staff of the Geneva General Hospital, held at the Hotel Seneca it was unanimously voted to organize a Geneva Academy of Medicine, and thereby transfer the scientific sessions of the staff over to the new organization. This would thereby eliminate all business matters pertaining to the staff from coming up at the scientific sessions. It would, in

other words, be an entirely separate organization.

"The staff adjourned in order to hold a preliminary meeting of the newly formed Academy of Medicine. At this meeting, which was discussed by every member present, several ideas were suggested, which were of important value to the committee on organization. The chair (Dr Knickerbocker) then appointed Dr Crance chairman of the committee on organization, who in turn appointed Drs John Shipman and John Robson to make up the committee.

"This committee met at the office of the chairman on the evening of April 21, 1925, and laid out several ideas and plans to be adopted at the next official meeting

"Practically every member has expressed himself as to the splendid character of the meetings both as to their scientific value, as well as their splendid social spirit. The buffet luncheons following the scientific programs add to this side of the meetings to a great extent

"It should be clearly understood that the Geneva Academy of Medicine proposes to grow and become one of the large clinical societies in this section of the state. It is steadily growing, and we wish to extend the glad hand of welcome to all physicians who are not already members to join now"

The society meets monthly and has an annual dinner meeting. Physicians in the vicinity of Geneva are eligible for membership

## QUEENS COUNTY MEDICAL SOCIETY

The regular meeting of the Medical Society of the County of Queens was held at the Jamaica Lodge, I O O F No 247, 159-29 90th Avenue, on March 29th, 1927. President, Joseph S Thomas, in the chair

The minutes of the February meeting, as published in the Bulletin, were approved

The following candidates having been approved by the Board of Censors were, on motion, duly elected by ballot cast by the Secretary: Leo Batell, M D, 7136 Loubert Street, Forest Hills, L I; Harry Vincent Cogne, M D, 3243 81st Street, Jackson Heights, L I; Charles A Lust, M D, 610 Thirteenth Street, College Point L I; Walter J Lynch, M D, 188-30 Central Avenue, St Albans, L I

Dr F G Riley reported for the Committee on Graduate Medical Education

President Thomas announced the death of Dr Charles H Peck. The matter of suitable resolutions was referred to the Comitia Minora

Dr D E McMahon reported for the Legislative Committee

The following Scientific Program was presented

1 Paper—General Management of Uterine Hemorrhage—By James A Corscaden, M D, Gynecologist, Sloane Maternity and Presbyterian Hospitals and Vanderbilt Clinic

The speaker said in part that bleeding from the uterus presents difficulties of diagnosis and management unknown in other organs due to the fact that the endometrium in humans and in anthropoid apes discharges blood when it shrinks from its greatly hyperplastic state, necessary for the lodgment and nourishment of a fertilized ovum. When a woman presents a history of abnormal bleeding, one must form a conception of the fundamental process underlying the symptom. From the standpoint of therapy, it is convenient to classify this bleeding under three headings

First Functional, meaning a variation of the mechanism which starts and stops and controls the regular twenty-eight day flow

Second Pregnancy, where the bleeding is

caused in many ways, but where our whole object is the preservation and ultimate delivery of a child. Here the bleeding is incidental except occasionally when it is profuse

Third Certain anatomical changes in the tissue result in bleeding (trauma, active and passive congestion, ulceration, diseases of the blood and blood vessels). Here again the bleeding is incidental. The disease is the object of our treatment

The management of pregnancy will not be discussed. Functional bleeding should be approached through the individual and not as a uterine problem, whether by general health, endocrines, or by some of the newer vitamins, such as that found in liver. If rational therapy fails, it is easy to terminate menstruation by excising the endometrium—which is fundamentally our purpose when we do hysterectomy, or by destroying the ovaries either by excision or by the selective action of X-ray or radium. The choice of method will depend upon expediency, age of the patient, or other similar factor. The principle will remain the same—to destroy menstruation you must either remove the endometrium or the ovary

The treatment of bleeding which is incidental to an important disease will come secondary to the treatment of the disease itself, except in the case of fibromyoma of the uterus. Here one must decide whether he is treating the tumor or whether he is treating the bleeding. If the tumor be the fundamental consideration, hysterectomy would seem to be the method of choice. If bleeding be the major consideration, the termination of it by an artificial menopause would be the method of choice

Discussion by Drs H P Mencken, E A Flemming, A L Voltz

2 Talk—Factors of Significance in Maternal Morbidity and Mortality, by E A Flemming, M D

Discussion by Dr Thurston Welton  
Attendance, 57

E E SMITH, *Secretary*

## A COUNTY HEALTH DEPARTMENT

The Suffolk County Medical Society is actively promoting the establishment of a County Health Department. The April issue of its Monthly News Letter explains the proposed department in the following article which will apply equally well to any other rural county of New York State—Editor's note

The proposed County Health Department is to consist of

- 1 A Board of Health
- 2 A Health Officer
- 3 An office and a clerk
- 4 Field workers,—two or three public health nurses

The present plan of a board of health and health officer in each town and village, 23 in number, is to be kept, but supplemented by the County Department

The kinds of health work to be done

- 1 Protective, in the presence of actual danger, will continue to be done by the present system
- 2 Preventive, preparing for trouble ahead of its appearance will be done by the County Health Department

### *Present System Is Protective Only*

Only two kinds of work are done under the present system

- 1 Sanitation—Sewage, water supplies, garbage, pigpens, noises, etc
- 2 Contagious Diseases—Reporting, quarantine, etc

The County Health Department will amplify and supplement the present protective system with more efficient *Preventive* work

An example of the kind of work to be done by the County is the tuberculosis work, which is now unified and effective. The plan adopted in tuberculosis work will be extended to other phases of public health work

The kind of work to be done by the County Department of Health may be grouped under six activities

### *First Activity — Consultations with Local Health Officers*

The county health officer will be a full-time specialist, available for the local health officers to consult, especially when their problems involve adjoining districts over which they have no jurisdiction. The State has supplied some consultation service through its district State health officers, but the work is so great that a consultant is needed in every county

Present health officers to consult him in

- (a) Contagious diseases,—their recognition and management
- (b) Water Supplies,—Surveys of water sheds, interpretation of analyses co-ordina-

tion of control when a company serves two or more villages and towns

(c) Milk Supplies,—Bootlegging in milk, selling milk in several health districts, getting analyses made

(d) All other problems, child welfare, health education, etc

### *Second Activity—Statistics*

No one now knows much about the amount of health work, done in the county, except that in tuberculosis. Secure figures regarding all kinds of work, contagious diseases, milk, water analyses, laboratories, etc

### *Third Activity—Laboratories*

There is a great need for them to be located in hospitals

There is difficulty of obtaining service by the state

The state still to be available in emergencies, and the more complicated matters, but local service is needed in such matters as milk analyses

No village or town can afford it, but the county can readily conduct it

### *Fourth Activity—Nursing*

Two or three nurses to be a field force available to special investigations. Example, a scarlet fever outbreak. Seek out the cases

Tuberculosis, more nurses are needed in that field

### *Fifth Activity—Health Work Among Children*

Advise and assist the local school medical inspectors

Get records of the work

Put the work on a higher plane

Get results

### *Sixth Activity — Public Health Education*

Newspaper articles

Lectures

Personal conversations

All for the purpose of explaining the health conditions in the county and the means of making them better

The Suffolk County Medical Society is engaged in that work, and publishes a monthly News Letter

In conclusion, the County Health Department will do for Suffolk County what the Department does for a city of 100,000 to 200,000 population, such as Albany and Utica

It is impossible to extend the present system

Introduce the county system to bridge the gap between the towns and villages on the one hand and the state on the other

The cost

The estimated annual cost of an efficient County Health Department is \$20,000. The present system of town and village health boards is costing over \$20,000 annually, and to bring their work up to an efficient standard will cost much more than an additional \$20,000, if indeed sufficient cooperation could be obtained to make their work at all efficient.

The state law provides that the state shall bear one half of the expense of a County Health Department. The cost of Suffolk County may therefore be estimated to be \$10,000 annually.

The Board of Supervisors is the authority that is empowered to establish a County Health Department.

## BRONX COUNTY MEDICAL SOCIETY

A regular meeting of the Bronx County Medical Society, held at Concourse Plaza, on March 16, 1927, was called to order at 9 P. M., the President, Dr. Friedman, in the Chair.

The following physicians were elected members: Drs. Paul H. Bernstein, Edwin B. Bilchick, Harold Fay, William V. Gilbert, Frank Ward Goeller, Marie Pichel Levinson, Sidney B. Roof, Alexander Schiff, Kathryn Wheeler Small.

A report was received from Dr. Weitzner, Chairman of the Social Committee, regarding the Beefsteak Dinner held on February 28th, and the next step in the program which is to introduce a group of outdoor sports.

Dr. Boas, Chairman of the Committee on Public Health and Medical Education, presented a report announcing doctors who have agreed to speak before lay audiences and calling for further applications. The Committee also reported regarding the folder being prepared by The New York Tuberculosis and Health Association, and the question of giving radio health talks as well as the advisability of circularizing periodic health examination folders through the schools. The President urged the members that as soon as they are informed that the folders are ready for distribution they send either the names of their patients to the Bronx Committee of the New York Tuberculosis Health Association or send it word that they are ready to receive the folders so that they may address them to their patients.

It was moved and carried that in connection with the imprint of the New York Tuberculosis Health Association, there be a statement in the folder that it has been approved by the Bronx County Medical Society.

Dr. Lukin, for the Committee on Medical Economics, reported progress.

Dr. Cunniffe, for the Committee on Legislation, reported regarding various bills that have been introduced in the legislature affecting the medical profession, including bills regarding chiropractors and amendments to the Workmen's Compensation Law. Assemblyman Berg has introduced a bill which would grant to the veterans of the last war the right to practice physiotherapy under the direction of a physician, these men being graduates of one of the Government schools which would give them a very good training.

Dr. Cunniffe also reported regarding a vacancy on the Board of Regents and expressed the opinion that at least one member of the Board should be a physician and recommended that the Society should urge the Chairman of the State Committee on Legislation to impress upon the legislature the demand of the medical profession to have a physician on the Board of Regents.

It was moved and carried that the report be approved and that the secretary be instructed to write to the Chairman of the State Committee on Legislation as recommended in the report.

Dr. Goldberger, for the Committee on Hospitals, reported progress.

Dr. Jacobs, for the Building Committee, reported progress and stated that the Committee would be in a position to report definitely at the next meeting.

Dr. Henry Roth, for the Relief Committee, reported that the Committee is trying to gain information from other Societies and is not quite ready to report definitely now.

In regard to the "Physician's Questionnaire" from the office of the Federal Prohibition Administrator, which was referred to the Counsel of the State Society, Mr. Stryker advised "that there is nothing compulsory about the filing in, executing, or returning of this form. The public administrator has taken this method of determining who are the persons lawfully and legally entitled to receive liquor permits and to aid the prohibition administrator in the proper functioning of the law and prevent the prescription permits from falling into the hands of persons not lawfully entitled thereto."

The Scientific Program then proceeded as follows:

### PAPERS

1 "Primary Streptococcus Peritonitis in Children," Joseph Schwartz

2 "The Significance of Abdominal Rigidity in Children," William Klein

3 "The Diagnosis and Treatment of Meningitis in Children," Linnaeus E. La Fetra

The papers were discussed by Drs. Henry Roth, Sidney V. Haas, Charles Herrman, Joseph Popper, William L. Rost and Abraham Lobell.

I. J. LANDSMAN, M.D., *Secretary*

A regular meeting of the Bronx County Medical Society, held at Concourse Plaza, on April 20, 1927, was called to order at 9 P M, the President, Dr Friedman, in the chair

Election of candidates being in order, it was moved and carried that the secretary be instructed to cast one ballot for the following candidates for membership

Augustine J Annunziata, Samuel Austrian, Harold Burg, William Fraden, Henry L Greene, Henry Harris, Bernard Kurz, James A Lynch, David Newman, Samuel Strumwasser

Reports of committees being in order, the Committee on Legislation reported that none of the chiropractic bills introduced at the last session of the state legislature passed and that all amendments to the workmen's compensation failed of passage

The Committee on Public Health and Medical Education reported that it is working on the folder being prepared in conjunction with the New York Tuberculosis and Health Association

Dr Lukin, for the Committee on Medical Economics, reported on the subject of "Open Hospitals," and urged that the Bronx County Medical Society hold a special meeting on open hospitals in the near future, similar to meetings being held by other medical societies

It was moved and carried that we hold a special meeting in the near future to consider the subject of "Open Hospitals"

Dr Weitzner, for the Social Committee, re-

ported with special reference to the organizing of golf and swimming groups

Dr Gitlow, for the Relief Committee, reported regarding the establishment of a relief fund for our members by the society After discussion it was moved and carried that the report of the Relief Fund Committee be referred to the Comitia Minora for further study and final report to the society

Dr Podvin for the Bulletin Committee asked for the cooperation of the general membership in the preparation of articles for The Bulletin

The secretary read a communication from the Department of Health on the subject of National Health Week for Children to be celebrated in the City of New York from May 1st to May 7th, and stating that it is believed that the value of diphtheria prevention should be the outstanding matter of interest in all activities

The scientific program then proceeded as follows

Papers

- 1 "Factors in Nutrition," Joseph H Gettinger
- 2 "The Practical Treatment of Toxemias of Pregnancy," George W Kosmak

It was moved and carried that a vote of thanks be extended to the readers of the papers of the evening

Respectfully submitted,

I J LANDSMAN, M D,

Secretary

## RICHMOND COUNTY MEDICAL SOCIETY

The Medical Society of the County of Richmond met on April 22nd and discussed the recent decision of City Magistrate Bridges which was fully discussed by Mr Lloyd Stryker in the Legal Department on page 498 in the May first issue of this JOURNAL When a case against a chiropractor for illegally practising medicine was tried, Magistrate Bridges dismissed the case with the following decision

"When a person, claiming to be suffering pain, seeks out another and asks for treatment for that condition, well knowing that such person does not claim to be a regularly licensed physician, as in this case, and such person does treat said applicant by manipulating or rubbing, I can see no violation of the Statute, nor do I believe the legislature intended it to be so regarded Otherwise, every masseur and chiropractor (so called) in the state would be put out of business

There was, in this case, no illegal treatment or prescription

Complaint dismissed—Defendant discharged"

The Richmond County Medical Society adopted a resolution setting forth the facts which have already been told by Mr Stryker and ended with the following resolution

'THEREFORE BE IT RESOLVED, That it is the sense of the Medical Society of the County of Richmond, interested as it is in the safeguarding of the health of the people of its community, and in the enforcement of the public health laws with reference to the unauthorized practice of medicine that the decision of Magistrate Bridges is viewed with regret"

WILLIAM R JANEWAY, M D, *President*,  
West New Brighton, Staten Island  
CHARLES RIEGER, M D, *Secretary*

# THE DAILY PRESS

## LEPROSY ERADICATION

The daily papers have recently carried accounts of a campaign to raise \$2,000,000 to assist the Philippine Government to eradicate leprosy from the Islands. Governor General Wood is a physician, and therefore has a first-hand appreciation of the importance of the study of leprosy and the eradication of the disease.

The *New York Tribune* of April 12 contains a personal letter from the Honorable Henry L. Stimson in which he says:

"I have had the opportunity of knowing intimately the plans that have been carried out under Governor Wood's direction at Culion, the greatest leprosarium in the world, and of the needs with which he is confronted at the present time. It is quite evident that if adequate funds can be given to this work we shall see in the Philippines in the combating of leprosy a repetition of what we saw in Cuba with yellow fever. Leprosy can be cured and is being cured for they have already dismissed more than 1,000 inmates at Culion."

"One of America's best leprologists and pathologists is stationed at Culion, Dr. H. W. Wade. The fight that he is waging in co-operation with Governor Wood and other American and Philippine doctors is of world-wide importance and deserves the fullest support of generous-minded Americans."

The *New York Herald-Tribune* of April 11 says editorially:

"When the leper colony of Culion was established twenty years ago there was little hope of curing the disease, but the segregation of many of the afflicted in surroundings that mitigated their distress was a forward step. Now, however, the treatment of leprosy has so far advanced that 50 per cent of the Culion cases show 'improvement,' and 10 per cent of the patients in whom the disease is not of many years' duration are in the 'curable' class. One thousand lepers have been discharged from the colony, their malady overcome. The achievement thus far in the Philippines, forwarded by the unremitting zeal of General Wood, gives promise that leprosy can be eradicated from the islands if the facilities for combating the disease known to modern medicine are fully provided."

The Culion leper colony is located on an island about two hundred miles south of Manila. It receives about one third of the total appropriations for public health made by the Philippine Government.

The subject of leprosy was discussed editorially on page 940 of the November 15, 1926, issue of this JOURNAL in which comments were made on the *Indian Medical Record* for September, 1926, which was a special leprosy number.

## THE CRIMINAL FACE

There is a well-known type of face which a cartoonist draws when he wishes to indicate a criminal, but those who work in prisons seldom see that or any other predominant type. If criminality expresses itself, in outward forms, the identification and apprehension of criminals would be easy.

However, any distinguishing mark of prominence is a grave burden to a criminal, especially when he seeks honest work after his release from prison. The daily papers have recently commented freely on the application of plastic surgery to the faces of convicts in the California State Prison at San Quentin. The *New York Sun* of April 7, says:

"Plastic surgery has remodeled the ugly countenance of Jim Daly, fifty-five-year-old convict, who is about to be discharged from San Quentin. Believing he was about to be turned into a world which should slam the door of success in his villainous looking face, Daly requested Dr. Leo

Stanley, prison physician, to perform the operation.

"Dr. Stanley, who had studied plastic surgery, consented. He pared Daly's cauliflower ear down to normal size and used the pieces to fill a gap in his nose."

"An iron mask could have been no more effective in concealing his identity. When he told his fellow prisoners, those who felt the same affliction also applied to Dr. Stanley for help. The physician said twenty-two others have asked for operations, some of which already have been performed."

"The prisoners insist that with facial alterations they would be free to really become 'new men' to the outside world, that they could pass by the 'old gang' and the ever suspicious detective without giving away their identity."

"Dr. Stanley said he would comply with all requests thus far received."

The medical profession approves Dr. Stanley's attitude.

## MAIL SOLICITATIONS FOR FUNDS

Mail orders have invaded even the field of solicitation of funds for charity. A doctor receives a brilliant necktie by mail, to be worn three days and if satisfactory, the price, one dollar, is to be sent, otherwise the tie is to be returned at the sender's expense. Doctors and others follow the easiest course and remit their dollar bills. If a considerable proportion of such mail went into the waste basket, the practice would die a natural death.

Philanthropic organizations send out beautiful subscription books, each one numbered and accompanied with a stamped and addressed envelope for return presumably with a dollar bill or a larger check. If a majority of these, too, went into the waste basket, doctors would soon escape the annoyance of being solicited for funds for objects in which their interest is only impersonal.

Mail solicitations have been taken up by thieves, as is shown by the following editorial note from the *New York Times* of April first:

"A flagrant example of fraudulent use of funds solicited in the name of charity has just

come to light. Letters from the Crippled Children's Relief Association, Inc., enclosing three initialed handkerchiefs, price one dollar, were sent out to 'prospects'. Kind-hearted persons sent back five, ten and sometimes a hundred dollars, and usually returned the handkerchiefs as well. It appears to have been one or two individuals who got up the scheme for getting an easy living from the charitably inclined. They made no pretense of maintaining an institution. In a Lexington Avenue loft they had a desk and chair, sufficient paraphernalia for mulcting the guleless.

"The plan of the reputable charities of this city—to compel all such organizations to file a report of their collections and disbursements—would automatically rule out illegitimate concerns. Newly formed societies would also be forbidden to operate until their credentials were recorded. Fraud in charity should be made more difficult."

The waste basket is a safe and efficient depository of begging letters and merchandise received by mail from unfamiliar parties.

---

## A RADIO CODE IN MEDICINE

Medical emergencies at sea occur with such frequency that the American Code Company, publishers of telegraphic and cable codes, is planning a code to facilitate the transmission of messages relating to the diagnosis and treatment of human ailments. The *New York Times* of March 31 says:

"The company had been working on the idea in conjunction with well-known New York medical men and steamship companies for the past six months. The plan has been approved in principle by all who have discussed it, and the

company hopes to get the cooperation of the medical associations in working out the code system. The outline of a practical book to be used in the treatment of diseases in accordance with instructions received by code has been prepared and is meeting with unqualified approval.

"Radio medical service was first established by the Seamen's Church Institute. Private and Government radio and telegraph stations have transmitted such messages to any ship without charge."

---

## PREVENTIVE CLINICS

The saving to hospitals by the establishment of preventive clinics has been discussed extensively from the viewpoint of the patient and charity. The *New York Times* of April 4 discusses the subject from the standpoint of hospital administration.

"The rising cost of hospital administration has brought about to some degree the establishment of clinics and out-patient departments. They treat serious diseases in its early stages, check minor diseases and defects and do admirable work as centres of prevention. A large part of this work has been made possible by the grant

of funds from the Rockefeller Foundation.

"With the cost of hospital care still going up it is apparent that clinical preventive work is an enormous economy, both for the patient who is able to pay and for the community which takes care of those who cannot pay. The difference in the cost of treatment is striking. Without physicians' fees, in both cases, hospital service costs at least \$5 a day, high-grade out-patient care costs about \$5 a month. Subsequent cost in suffering and money, when scarcity of clinics prevents cheap and early diagnosis, is incalculable."

"The prisoners insist that with facial alterations they would be free to really become 'new men' to the outside world, that they could pass by the 'old gang' and the ever suspicious detective without giving away their identity."

"Dr. Stanley said he would comply with all requests thus far received."

The medical profession approves Dr. Stanley's attitude.

# BOOK REVIEWS

**THE SURGERY OF GASTRO-DUODENAL ULCERATION** By CHARLES A. PANNETT, B.Sc., M.D. Octavo of 154 pages, with illustrations. London and New York, Oxford University Press, 1926. Cloth, \$3.25 (Oxford Medical Publications).

This little book, one of the later additions to the list of monographs published by the Oxford Press, is a welcome addition to the family. These books are singularly alike in the fact that they look like primers and are found on examination to be a good deal more.

In this case the subject under consideration is covered simply and neatly. The gaps in our knowledge are indicated and temporarily filled with good shrewd conjecture.

The "Principles" of our empiric surgery are once more enunciated and the various types of partial resection of the stomach are illustrated and described. Much more elaborate discussion of this subject may readily be found but—after all—is there so much to say?

J. E. JENNINGS

**BRAIN AND HEART** Lectures on Physiology By GIULIO FANO. Translated by HELEN INGLEBY. Octavo of 142 pages, illustrated. London and New York, Oxford University Press, 1926. Cloth, \$2.75 (Oxford Medical Publications).

This book is the work of a scientist who is also a philosopher and a man of letters. The author relates certain of his scientific experiences, using them as texts for large discourse. From experiments on the marsh tortoise, he learns lessons which touch on the origin and purpose of life. One-third of the book is taken up with two chapters on the so-called Living Matter. He feels the want in Darwin's theory of evolution of a determining force, and satisfies it with the assumption of a potent "Cosmic Will," of an unending purpose running through the ages, as the poet has already said. In the third and fourth chapters, on Inhibition and Will, the author shows, from experiments on the tortoise, how will is manifested by inhibitory acts. In the fifth chapter, on Excitability and Automatism, certain questions of cardiac physiology are discussed: the rhythmic action of the heart and the respiratory mechanism are accepted as due "to a nutritive cycle in the cells which perform the movement." The last chapter deals with the Relations between Excitability and Automatism Determining Cardiac Peristalsis. The reader who appreciates philosophy, as well as science, will delight in this book.

E. E. CORNWALL

**SURGERY OF CHILDHOOD** By JOHN FRASER M.C., M.D. Two octavo volumes of 1152 pages with illustrations. New York. William Wood and Company, 1926. Cloth, \$14.00.

In his preface the author makes some apology for the length of the production but to the reader, the division of the work in two volumes, gives the impression of completeness with no thought of unnecessary length. When one bears in mind that the surgery of childhood must include a great part of general and special surgery, with such additional information as is necessary, in many instances in the application of these general principles to the child, the difficulty of covering so broad a subject in a more limited space is apparent.

The author divides his work in two parts which do not coincide with the publishers' division of the work into two volumes. Part one includes a discussion of general principles and general and localized pathology, part two being devoted to regional surgery, beginning with surgery of the head.

There is one Appendix, on the Method of Making Celluloid Splints, and a very complete and satisfactory index at the end of Volume Two.

The basis of this excellent study by Doctor Fraser is formed by the lectures and clinics delivered at the Edinburgh Royal Hospital for Sick Children, and the results are a book on the surgery of childhood in fact as well as in theory. "Surgery of Childhood" by Doctor Fraser is a desirable addition to the library of the general surgeon, but it contains, also, much that will interest and instruct the pediatrician and the general practitioner.

J. C. C.

**A PRACTICE OF PHYSIOTHERAPY** By C. M. SAMPSON, M.D. Octavo of 620 pages, with 146 illustrations. St. Louis, The C. V. Mosby Company, 1926. Cloth, \$10.00.

One is rather prejudiced in reviewing the work of an author when the reviewer has been in actual contact and personal touch with the work as expounded in the discussed volume.

Major Sampson, with his tremendous experience in rehabilitation work among our returned, wounded soldiers from the late Great War, is certainly an authority that one must respect. His work, or text book, touches deeply into a field in therapy that has been very much clouded and uncertain until real scientific research upon a very large number of patients has placed it in the same category as the Dispensatories of our drug therapy.

Besides having this unusual experience the author writes as he speaks in a very breezy and much understandable language. This volume, although of text book size attracts the reader so much that one is tempted to read it through when first receiving it. It is not placed away in our bookcase to be used for reference only.

In his book, Major Sampson has rendered a real service by systematizing the material into a comprehensive explanation of the different modalities of physiotherapeutic practice. This is combined with a few chapters on clinical applications especially laying stress on Peripheral nerve injuries, Acute Gonorrhea in males, Arthritis Locomotor Ataxia, Hay Fever and Pyorrhea Alveolaris.

In these chapters on clinical applications, if one was not familiar with the work of the author some of the statements made would appear very radical, because they do not entirely conform with our concept of the pathological conditions that exist in these various diseases. But there are many results obtained in our armamentarium of drug therapy and surgery that do not aim for the removal of the pathology in the relief of symptoms. His attitude is at times very conservative not claiming any cures but clinical relief in such conditions wherein, this, has not been accomplished by any other known means.

It is a very valuable and timely work which should not only be possessed by all those that are using Physiotherapy but also by every practitioner and specialist of medicine and we feel can safely be recommended as a text book for medical students.

B. KOVEN

**FRESHMAN HYGIENE** Personal and Social Problems of the College Student. By RAYMOND C. BULL, A.B., M.D., and STANLEY THOMAS, M.S., M.A. Octavo of 288 pages with 74 illustrations. Philadelphia and London, J. B. Lippincott Company, 1926. Cloth, \$2.00.

This is one of the best books of its kind ever brought to our attention. We recommend it not only to college freshmen but to high school seniors and to that vastly larger group of boys and girls of similar ages who are

# BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

**MEDICAL ORGANIZATION AND MEDICAL BIOGRAPHY OF SENECA COUNTY, NEW YORK** Compiled by LESTER W. BELLOWS, M.D. Octavo of 429 pages. West Henrietta, New York, Manzler Publishing Corporation, 1926. Cloth, \$4.50.

**A MANUAL IN PRELIMINARY DIETETICS** By MAUDE A. PERRY, B.Sc. 16mo of 146 pages. St. Louis, The C. V. Mosby Company, 1926. Cloth, \$1.25.

**MEDICAL CLINICS OF NORTH AMERICA** Vol. 10, No. 4 January, 1927 (New York Number). Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues). Cloth, \$16.00 net, paper, \$12.00 net.

**SYMPTOM DIAGNOSIS REGIONAL AND GENERAL** By WILFRED M. BARTON, A.M., M.D., and WALLACE M. YATER, A.B., M.D. Octavo of 851 pages. New York and London, D. Appleton and Company, 1927. Cloth, \$10.00.

**THE PRACTICAL MEDICINE SERIES** Comprising Eight Volumes on the Year's Progress in Medicine and Surgery. Under the General Editorial Charge of CHARLES L. MIN, A.M., M.D. Series, 1926. Chicago, The Year Book Publishers, 1926. General Surgery. Edited by EVARTS A. GRAHAM, A.B., M.D. 12mo of 726 pages, illustrated. Cloth, \$3.00. Price of the series of eight volumes, \$15.00.

**PRINCIPLES OF PHYSICAL CHEMISTRY FOR MEDICAL STUDENTS** By PHYLLIS M. TOOKEY KERRIDGE, M.Sc. With Introduction by PROF. A. V. HILL, M.A., F.R.S. 12mo of 134 pages, illustrated. London and New York, Oxford University Press, [1927]. Cloth, \$1.75 (Oxford Medical Publications).

**MANUAL OF OPERATIVE SURGERY** By SIR HOLBERT J. WARING, M.S., M.B. Sixth Edition. 12mo of 868 pages, illustrated. London and New York, Oxford University Press, [1927]. Cloth, \$5.25 (Oxford Medical Publications).

**MANUAL OF MEDICINE** By A. S. WOODWARD, C.M.G. Third Edition. 12mo of 523 pages. London and New York, Oxford University Press, [1927]. Cloth, \$4.75 (Oxford Medical Publications).

**DISEASES OF THE HEART** Their Diagnosis, Prognosis, and Treatment by Modern Methods. By FREDERICK W. PRICE, M.D. Second Edition. Octavo of 534 pages, illustrated. London and New York, Oxford University Press, [1927]. Cloth, \$6.20 (Oxford Medical Publications).

**THE ENLARGED PROSTATE** By KENNETH M. WALKER, F.R.C.S. Octavo of 193 pages, illustrated. London and New York, Oxford University Press, [1926]. Cloth, \$4.00 (Oxford Medical Publications).

**SOME GERMAN SPAS** A Holiday Record. By S. L. BENSUSAN. [Second Edition]. Octavo of 172 pages, illustrated. London, Noel Douglas, [1926]. (Copies can be obtained for \$1.50 by applying to the German Health Resorts at 630 Fifth Avenue, New York City.)

**DEUTSCHER BÄDERKALENDER** Herausgegeben vom Allgemeinen Deutschen Bäderverband. E. V. REDIGIERT VON PROF. DR. WEISSBEIN. Octavo of 375 pages, illustrated. Berlin, Bäder- und Verkehrs-Verlag G.m.b.H., 1926. (Copy free to physicians upon application to German Health Resorts, 630 Fifth Avenue, New York City. Cost to others \$1.00.)

**EARLY DAYS OF THE PRESBYTERIAN HOSPITAL IN THE CITY OF NEW YORK** By DAVID BRYSON DELAVAN, M.D. Octavo of 191 pages, with 34 illustrations. Published privately, 1926. [East Orange, N. J., The Abbey Printshop, Inc., 1926]. Cloth, \$1.50. (Copies may be obtained by applying to the Joint Administrative Board, 17 East 42nd Street or to the Presbyterian Hospital in the City of New York, 41 East 70th Street.)

**MODERN CLINICAL SYPHILOLOGY** By JOHN H. STOKES, M.D. Octavo of 1144 pages, with 885 illustrations. Philadelphia and London, W. B. Saunders Company, 1926. Cloth, \$12.00.

There have been so many new remedies and new methods of applying remedies directed towards the eradication of the spirilla pallida from the human body that even among the specialists treatment is not yet standardized.

The management of syphilis is a problem which concerns every medical man almost daily. Frequently the internist, the surgeon, the obstetrician, the pediatrician, et cetera, wish to know the best methods about which to advise their patients.

This book by Dr. Stokes is the best and most modern presentation of the subject. Get it and read it no matter what your particular field of therapy is. In a book of such splendid excellence there seems hardly any reason to emphasize any portion over another, but for the surgeon we would say read it if only for the chapter on "Late Syphilis of the Skeletal System," and, to the internist the chapter on "Syphilis of the Cardiovascular System" is equally valuable. The presentation of syphilitic involvement of the nervous system is clear and full. The information is given in a way to be of definite clinical value to everyone. Again we repeat, with more enthusiasm than usual, that this is a book which should be on the desk of every practitioner.

J. STURDIVANT READ

**HYGEIA OR DISEASE AND EVOLUTION** By BURTON PETER THOM, M.D. 16mo of 107 pages. New York, E. P. Dutton & Co., 1926. (Today and Tomorrow Series.)

This little publication is a more or less instructive book for the layman. We cannot, however, recommend very highly a contribution in which we find typhoid vaccine called antityphoid serum and rabies vaccine antirabic serum, in addition the latter according to the author is used to prevent and cure rabies, a disease which is recognized as hopeless once it has manifested itself.

E. H. M.

**A HANDBOOK OF RENAL SURGERY** By F. MCG LOUGHNAKE, F.R.C.S. Octavo of 210 pages with 46 illustrations. New York, Longmans, Green & Co., 1926. Cloth, \$3.75.

This little volume of about two hundred pages is somewhat in the nature of a compend and is prepared, as stated in its preface, for the student and the general practitioner. It presents in a very condensed form an outline of the present day knowledge of renal surgery and makes no pretense at covering details. It should be of value to the student preparing for examination or for the general practitioner who wishes to familiarize himself with what is being done in this branch of surgery. There are a number of very good illustrations.

N. P. R.

**THE HEART** By ALEXANDER GEORGE GIBSON, D.M., F.R.C.P. 16mo of 108 pages, with 15 illustrations. London and New York, Oxford University Press, 1926. Cloth, \$1.50. (Oxford Medical Publication.)

This interesting little book with its 108 pages of meagre dimensions four by six and one-half inches, gives evidence on every leaf that it has not been prepared by a neophyte. Alexander Gibson's name on the title page is the answer.

The distinguished author has condensed in a remarkable way the facts and fundamentals of modern cardiology. The result is a delightful review of present day conceptions of heart function and disease. The reviewer recommends it without hesitation to students and practitioners.

A four-page bibliography of unusual discursive character and value concludes the volume.

FRANK BETHEL CROSS

**PRINCIPLES OF DIAGNOSIS AND TREATMENT IN HEART AFFECTIONS** By SIR JAMES MACKENZIE, M.D., and JAMES ORR, M.B., Ch.B. Third Edition. Octavo of 242 pages with 35 illustrations. London and New York, Oxford University Press, 1926. Cloth, \$3.50. (Oxford Medical Publications.)

The demand for a third edition of this work proves the value of the authors' presentation of the subject. Those who are not acquainted with the authors' views on the heart and its action will be more than pleased at the information and reasoning presented in this volume. It is clear, concise, accurate, rational and presents in a logical manner much concerning the heart, and the care of the heart. Those who are acquainted with Mackenzie's views on the heart will recognize in this volume the views of the author after many years of study and teaching. The book is an excellent presentation of the subject.

HENRY M. MOSES

**PROBLEMS OF HUMAN REPRODUCTION** By PAUL POPENOE. 12mo of 218 pages. Baltimore. The Williams & Wilkins Company, 1926. Cloth, \$2.50.

This book will likely be read by a great many people approaching marriage, and the reviewer has the impression that they will search in vain for the knowledge which they so eagerly seek. The general matter in this book is about what everyone knows. There is frequent reference to the fact that the husband should know how to give his wife sexual happiness. The author fails to tell how the husband is to bring this about. The inexperienced man in sexual matters reads these books in order to learn technique, and if the author really wants to help out, he can give the technique that is most likely to help the husband to arrive at this point. If the author would read Dr. Long's book on "Sane Sex Life," he could make subsequent editions of his book of more advantage to the reader.

J. ARTHUR BUCHANAN

**HUNTER TOD'S DISEASES OF THE EAR**. Second Edition. Revised and Largely Rewritten by GEORGE C. CATHCART, M.A., M.D. 12mo of 333 pages, with 87 illustrations. London and New York, Oxford University Press, 1926. Cloth, \$3.50. (Oxford Medical Publications.)

In this second edition the revisor has entirely rewritten this well known work. The illustrations have been more than doubled. Being a hand book the material is much condensed, but each subject is well covered and brought up to date. It is a work written specially for the senior student to whom it can be highly recommended, but the general practitioner will also find it of value.

J. W. D.

**HUMAN PATHOLOGY**. A Textbook. By HOWARD T. KARSNER, M.D. With an Introduction by SIMON FLEXNER, M.D. Octavo of 980 pages with 463 illustrations. Philadelphia and London, J. B. Lippincott Company, 1926. Cloth, \$10.00.

This new book on pathology presents both the general and special pathological processes to which the body is subject. The text is well arranged and presented with unusual clarity. It covers the fields of pathological anatomy, pathological histology, pathological physiology, general bacteriology, and immunology. It is profusely illustrated, affording the reader a clear conception of the structural changes that occur in the body tissues during disease. It well serves the purpose of presenting the subject in a manner that does not require any extraordinary effort of grasping its meaning. It should prove very useful to both student and practitioner of medicine.

E. H. NIMISH

found in neither group. In dealing with sex hygiene the authors are to be commended for having omitted all references to the moral side of the question and confining their attention to the physiological aspect. The chapters on alcohol and tobacco are the sanest we have ever read in a work of this character. Physicians should recommend this book to those of proper age.

E. H. M.

**DEFECTIVE MEMORY, ABSENTMINDEDNESS AND THEIR TREATMENT** By ARNOLD LORAND, M.D. Octavo of 340 pages. Philadelphia, F. A. Davis Company, 1926. Cloth, \$3.00.

The author, who is practicing at Carlsbad, Czechoslovakia, has written a series of books dealing with various subjects primarily of mental hygiene nature. The latest book, *Defective Memory, and Absentmindedness*, deals at length with the nature of memory and its disorders, and with the treatment of the latter. After discussing the foundation of a good memory, and the recognition of pathological forgetfulness, he deals quite at length with the various causes of forgetfulness. A chapter is given to the treatment of forgetfulness. He then deals with the problem of absentmindedness. He then mentions many practical hints for assisting the memory. The treatment of ailments causing a poor memory is outlined in another chapter. There is a dissertation on the influence of the conscious and subconscious mind upon memory. To those who are interested in the subject, the book should have a great appeal. It has many practical suggestions and many valuable instructions that should be of help in dealing with defective memory.

IRVING J. SANDS

**THE INFLAMMATORY AND TOXIC DISEASES OF BONE. A Text-Book for Senior Students** By R. LAWFOR KNAGGS, M.C., F.R.C.S., with numerous photomicrographs by C. H. RODMAN, M.D. Octavo of 416 pages, 197 illustrations. New York, William Wood and Company, 1926. Cloth, \$5.50.

This book has to do with the inflammations and toxemias of bone—based on pathological and clinical studies. Dr. Knaggs, the author, has had the advantage of those great storehouses of pathology, the British Museums, such as the Museum of the Royal College of Surgeons, Guy's Hospital, Leeds and others, and he has drawn freely from these sources for his clinical histories and tissue. It is ridiculous to attempt to summarize a work of this character in a brief review but consideration of the chapter on acute osteomyelitis is sufficient to impress the reader with the high type of the book. The descriptions are clear and vivid, the deductions logical and, as a text for senior students, it has few equals.

The author has produced this book in the fullness of his years and the fruit is ripe and mature, a masterpiece in its particular field. May it pass through many editions and be translated into many languages.

J. C. R.

**A GUIDE FOR DIABETICS** By WALTER R. CAMPBELL, M.A., M.D., and MAME T. PORTER, B.Sc. Octavo of 259 pages. Baltimore, The Williams and Wilkins Company, 1926. Cloth, \$2.50.

The original work in the discovery of insulin was so thoroughly done by that group of workers in Toronto, that none of it has been proven false, and all of it has been verified. Doctor Campbell was a member of that first group, and the manual for *diabetics* which he has prepared is as thoroughly and sensibly worked out as was the first experimental work in insulin. He gives enough of the details that pertain to the disease, and its complications, and explains sufficiently the relation of the pancreas and other factors to diabetes. In so doing he has reserved most of his space for the discussion of foods and diets, and the apportionment of daily food allowance into meals. His rules for procedure are as simple as any which have been offered and he has two

innovations in his manual: a page out of every two in the book is plain and reserved for menus and notes, and there are a series of equivalents for substitution of single items of a menu which will greatly facilitate the changes or varying of diet which are so necessary. Nearly a half of the book is given to recipes. Such a manual is invaluable to the diabetic, and for the physician who wishes to do some really careful work, with his diabetics, no manual that has yet appeared will make it as easily possible to do so.

L. C. JOHNSON

**WHAT'S BEST TO EAT?** By S. HENNING BELFRAGE, M.D., M.R.C.S., L.R.C.P. With a Practical Supplement by LUCY H. YATES, M.C.A. Octavo of 199 pages. New York, William Wood and Company, 1926. Cloth, \$3.00.

This is a manual on diet, written for the British layman with hope, on the part of the author, that the material will also be of considerable help to his confreres. Doctor Belfrage writes in good steady British style, covering the ground thoroughly, beginning with the food elements through the main elements of diet, including the vitamins, and a discussion of the deficiency diseases. There is nothing new in his book but he does give a summary of the literature and attempts to make it palatable for the lay mind. There is a practical supplement by Lucy H. Yates, M.C.A., addressed to the layman's wife, which consists of rules for preparation of foods, and their arrangements into meals. The book is essentially British, and except for the main truths in the matter will not be particularly attractive for the American layman or his wife.

L. C. JOHNSON

**OUR MINDS AND THEIR BODIES** By JOHN LAIRD. 12mo of 122 pages. London and New York, Oxford University Press, 1925. Cloth, \$1.00.

In a compact volume of one hundred and twenty pages, the author, who holds the chair of regius professor of moral philosophy in the University of Aberdeen, has made a scholarly presentation of the mind and body, and the influence of one on the other. He discusses the subject from various angles. Thus the attitude of common sense as well as the evidence of science are thoroughly discussed in proving the relationship of mind and body. There is a chapter devoted to the hypotheses concerning the connection between mind and body. He also outlines the various metaphysical speculations regarding the subject, and treats of such subjects as Animism, Neutral Monism, Philosophical Dualism, etc. To one who deals constantly with neuropsychiatric subjects, the book is interesting and instructive. One cannot but feel that the soma and psyche are in reality different phases of an entity, the soma and psyche are one. To try to separate the two, would really lead one into old and disproven realms which, from a medical viewpoint, have also been found to be impracticable.

IRVING J. SANDS

**THE HUMAN BODY** By MARIE CARMICHAEL STOPES, Sc.D. Octavo of 268 pages, with 53 illustrations and color plates. New York and London, G. P. Putnam's Sons, 1926. Cloth, \$2.50.

To anyone interested in a clear, non-technical description of the anatomy and physiology of the human body, this book will prove of value. It is a very interestingly written book, and in spite of the fact it was written as a supplement to another book, it has sufficient character to stand well alone. In fact, it is a superior book to the one it was supposed to supplement. In spite of the fact the author has set out to make for racial improvement and sex repression, she does not overdo the subject in this book. Doctors may recommend this book to persons who are interested in knowing a little about how they are built, and we think most patients will be satisfied. It would also be useful for high school teachers as supplementary reading for courses in general biology.

J. ARTHUR BUCHANAN

The Management of an Infant's Diet

# Mellin's Food—A Milk Modifier

## Constipation

It is common observance among physicians who use Mellin's Food as a modifier of milk for infant feeding that their baby patients are seldom troubled with constipation, and if this annoying symptom does occasionally appear it is easily corrected by increasing the amount of Mellin's Food in the daily mixture or by some other slight readjustment of the formula

Some fault in the arrangement of the food formula is practically always the cause of constipation, so it seems logical to overcome the difficulty by rearranging the food elements to a more perfect balance rather than to employ medical means, which at best afford temporary relief only

In a pamphlet entitled, "Constipation in Infancy", the common causes of constipation are set forth for the physician's consideration, also practical suggestions for their correction. All of the matter presented is based upon observation extending over a long period and will prove of good service to every physician interested in the subject

A copy of the pamphlet will be sent promptly upon request. Samples of Mellin's Food also if desired

Mellin's Food Co., 177 State Street Boston, Mass.

# OUR NEIGHBORS

## THE HEALTH DEPARTMENT AND THE PRACTICING PHYSICIAN

Dr Henry F Vaughan, Health Commissioner of Detroit gave an address on the relation of the health department to the practicing physician before American Public Health Association in Buffalo on October 11, 1926, and illustrated it with descriptions of two contrasting methods of conducting campaigns for immunizations against diphtheria. He says

"In one group of cities the health department has made a determined effort to reach directly as many pre-school children as possible, irrespective of the financial condition of the parent or guardian. Special clinics have been opened, literature is mailed to the mother when the child is six months old, and a nurse may visit the home urging that the child be brought to a free clinic. Field nurses stimulate the attendance of young children, and a concerted drive is made upon the children during the months preceding his admission to school. Unofficial agencies and the insurance companies have done masterly work in encouraging clinic attendance, distributing literature and issuing reference cards for admission to the free clinics. Such a campaign is usually accompanied by much newspaper notoriety, paid advertisements, hand bills, and posters on street cars and sign boards. Such a procedure is indispensable at times of impending epidemic.

"In other cities the health department has established a very definite ruling that no individual financially able to engage the services of a private physician will be admitted to a public clinic, even for such prophylactic service as diphtheria immunization. The general educational program is the same as in cities of the first group, except in so far as the clinics are concerned. The nurses of the health department in visiting the home, invoke the interest of the mother, painstakingly explain what toxin-antitoxin is, and wherein it differs from antitoxin, describe the Schick test, and portray the need of its application as a means of ascertaining the child's resistance to the disease. Efficient employment of the art of

the crafty vendor of books, coupled with an alertness and eagerness to give prompt and sound reply to all questions, will almost invariably result in an expression of maternal interest and even enthusiasm. The mother is advised to consult the family physician and obtain the toxin-antitoxin treatment for her children at the doctor's office. There is no invitation to come to a free clinic. The nurse makes a list of all the pre-school children in the family and notes the name of the physician whom the mother has mentioned. A copy of the list will be sent to the doctor, and the medical men of the area have previously been brought together, the technic of toxin-antitoxin and the administration of the Schick test demonstrated, and the entire campaign outlined. The biological preparations are provided by the department of health, and for those financially responsible the physician makes his usual office charge, and for those unable to pay the health department reimburses the physician for his time without the knowledge of the patient and his family.

"There is much to commend a program of this character when the exigencies of the situation do not demand haste. The general practitioner of medicine is too frequently slow in keeping abreast with the advancement of preventive medicine. While we seldom meet the man who treats diphtheria with the elaborate synthetic compounds and irrigations of pre-antitoxin days, we do find vast numbers who have never read a Schick test. Is it not well that these physicians should conduct their practice with the full advantage of modern scientific methods, and how better can the health officer encourage this result than by creating a demand?"

"The physician will be forced to practice good medicine, or else he will lose his patient. There is great danger that the enlightenment of the laity will outdistance the physician's own advancement."

## PHYSIOTHERAPY

The April issue of the *Journal of the Medical Society of New Jersey* contains an article by Dr Spencer T. Snedecor on Physiotherapy in the Hackensack Hospital. It informs the general practitioners what physical therapy is and the methods of its application. The article is timely

in view of the attempts of unqualified persons to practice the specialty. It will enable general practitioners to visualize the various methods that are commonly used and the broad indications for their application.

(Continued on page 574, adv xii)

- (2) Internal
  - (A) Colonic Irrigation
  - (B) Vaginal Douche
  - (C) Gastric Lavage

## VI Mechanotherapy

- (1) Massage
- (2) Vibration
  - (a) Hand
  - (b) Mechanical
- (3) Exercises
  - (a) Active
  - (b) Passive

Nearly all these agents are used in the Hackensack Hospital with varying degrees of frequency and usefulness. They are applied only on prescription of the visiting physicians and surgeons and to those cases in which therapeutic results may be reasonably expected. During the past year 6432 patients have received 12,457 treatments, from which it will be noticed that each patient averages two different treatments on each visit. During the past month over 30 patients a day were treated in the department. The physiotherapy staff consists of a trained technician, two student nurses and an orderly. Every patient is examined before the first treatment and the exact prescription is outlined for the technician to follow. All treatments are supervised and the progress from time to time is noted.

"Our apparatus is listed as follows: 2 heat lamps, 3 bakers, 3 infra-red lamps (one very large), 1 air-cooled quartz lamp, 1 water-cooled quartz lamp, 1 carbon arc lamp, 1 large high frequency machine, 1 portable high frequency machine, 1 Morse wave generator, 1 Bristow coil, 1 whirlpool bath, 1 static machine.

"The foregoing list is suitable for a similar department in any general hospital, or for a doctor who wishes to go into physiotherapy extensively.

"The Hackensack Hospital has found the application of radiant heat effective in the following conditions: (1) For many aches and pains, such as myalgia, lumbago, arthritis, sprains, sciatica and other forms of neuritis. (2) For fractures in which early exposures improve the superficial circulation and lessen the edema. (3) For relaxing the muscles before any massage. (4) Before stimulating paralyzed muscles. (5) As a preliminary to ultraviolet ray treatment, as the stimulative short rays are absorbed better by tissues that have been heated.

"A third type of heat is produced deep in the body by the passage of an electrical current through the tissues. This form of heat is known as diathermy or converse heat. The tissues through which the electricity passes become heated in the same way that the filament in an electric light is heated. Its effects are deep and penetrating in contrast with the superficial effects of a hot water bottle or heat lamp. Diathermy will heat any organ or structure in the very cen-

# METABOLISM TESTING

## How It Will Help You

If you are equipped to determine a patient's Basal Metabolic Rate you can accurately diagnose many otherwise perplexing cases. You can identify with assurance the important thyroid disorders or eliminate the thyroid as a cause of the disease. You can study and treat more intelligently many special cases in diagnosis, therapy and surgery.

## Is the Test Simple?

Yes—with the latest Sanborn Metabolism Tester you or your assistant can make the test and get the Basal Metabolic Rate in less than 15 minutes without any complicated figuring.

Every detail is automatically recorded on a Kymograf chart that shows what occurred during each minute of the test and the patient's Actual Oxygen Consumption.

The Kymograf simplifies testing and makes results accurate and dependable. Well worth your while to learn more about it.

"The Hackensack Hospital is a general hospital of 250 beds, the only one among the 25,000 people of the city of Hackensack. To it come all classes of people, and its cases constitute a cross section of the medical practice of the city. Its physiotherapy department therefore affords the opportunity to estimate the field of usefulness as well as the limitations of physiotherapy in general practice.

"Physiotherapy is the application of physical measures in treatment and consists largely of the application of electricity to the various forms of abnormalities of the body. The electricity is sometimes applied directly for its stimulative effects, but is more often utilized as a source of heat and light. Next to electricity water is the agent most commonly used in physiotherapy, externally in the form of baths and sprays internally as irrigations.

## TUT-ANKH-AMEN'S COSMETIC

The *British Medical Journal* for January first contains the following description of the content of a cosmetic jar found in the tomb of Tut-Ankh-Amen

"The lid of the jar was cemented by a protective crystalline incrustation, an effect resulting from the action of moisture and saline matters contained in the dust of the local atmosphere. The contents of the jar weighed about 450 grams, or nearly a pound avoirdupois. It is described as rather sticky, and presenting the appearance of a heterogeneous mixture consisting of yellow nodules together with a chocolate-coloured substance. It became softened by the heat of the hand, and possessed a faint but distinctive odour which has been variously described as that of coco-nut or the flowers of broom, but rather valerianaceous. While the odour was decidedly fatty, there was no suggestion of rancidity. No vegetable structure or fibre could be distinguished by microscopic examination.

"It seems strange that the fats themselves had not wholly lost their fatty nature. This, however, they had preserved, but not without considerable modification of chemical structure. So far as could be judged from the chemical evidence, the fats had undergone hydrolytic cleavage into glycerol and free fatty acids, the glycerol remained largely unchanged, but the free fatty acids had combined with each other to form acid anhydrides, and those which were oxidizable had suffered oxidation—that is to say, such acids as oleic acid had acquired two or more hydroxyl groups. The investigations record the presence of 48 per cent of free and combined glycerol, which the authors state is largely, if not entirely, in the free condition, but we do not see how to reconcile this proportion of free glycerol with the diminutive quantities of matters set down as soluble both in alcohol and water in the general proximate analysis. Nothing of the nature of wax was found. Since the waxes are generally more stable than fats, this observation seems definitely to decide their absence. The fatty acids actually recognized were stearic, palmitic, and myristic acids, and smaller amounts of acids more nearly related to lauric or capric acid. The chemical evidence generally would seem to exclude coco-nut and palm-kernel oils, and it does not seem probable that any vegetable fat would have been available having the small proportion of olein computed to have been originally present. From these data Chapman and Plenderleith conclude that it is highly probable that the cosmetic was composed of about 90 per cent of an animal fat and about 10 per cent of a resin or balsam.

# OSCODAL

## Palatable Cod Liver Oil Therapy in Tablet Form

OSCODAL is a palatable cod liver oil concentrate containing the essential principles of the oil—the fat-soluble vitamins—with the following advantages

- (1) Elimination of objectionable bulk, nauseating odor and unpleasant taste
- (2) Accurate dosage.
- (3) Every lot is physiologically standardized
- (4) Oscodal is readily taken.
- (5) Oscodal is acceptable at all seasons

OSCODAL is marketed in bottles of 100 tablets  
Literature on request.

ter of the body to any degree of temperature for as long a period as one may desire. Actual thermometer measurements show that a vaginal temperature of 115 degrees is readily maintained. To accomplish this result without pain or damage to the tissues, diathermy requires a high frequency current, by which is meant an alternating current with impulses following one another in such rapid succession that living cells make no effort to respond to them. The common street current alternates 60 times a second, whereas the high frequency current alternates one to two million times a second.

"Medical diathermy is a constructive force that heats the tissues, bringing fresh blood supply and increasing metabolism. Surgical diathermy is a like force carried forward to the destruction of tissue by coagulation or cooking.

"The dosage or amount of heat the patient receives may be regulated in two ways, by changing the amount of street current which enters the transformer, and by widening the spark gap. Within limitations the wider the spark gap the greater the voltage and the heat. The technique of dosage is not difficult for any administrator to master. Generally speaking, the dosage is guided by the tolerance of the patient to a comfortable heat. One should always be watchful, but need not be unduly concerned about the possibility of burning a patient. In over 3000 diathermy treatments we have witnessed only one real burn and three or four blisters from sparking at the edge of the electrode.

"The uses to which this form of diathermy may be put are many and varied. Better than mastering all the possible applications is for the physician to learn the simple fact that the purpose of diathermy is to create heat and hyperemia in the tissues. Diathermy is therefore contraindicated where there is danger of hemorrhage or of pus without free drainage.

"In the Hackensack Hospital its use is wide and the results are excellent in the following treatments: (1) For stiff joints resulting from fractures or arthritis, (2) for infections with drainage, (3) for pain in fractures, strains, bruises, neuritis and sciatica, (4) for some types of hypertrophy of the prostate, (5) for gonorrhea—epididymitis and buboes in male, vaginal and pelvic infections in female, arthritis and posterior urethritis, (6) for maintaining nutrition in paralyzed muscles, (7) for calcification of bursæ, (8) for arthritis—sometimes quite effective and again disappointing."

## THE COMMONEST FOCAL INFECTION

What is the most common focal infection? This question is answered by Dr Edward E. Cornwall of Brooklyn in the following article in the April issue of the *Long Island Medical Journal*—EDITOR'S NOTE

"The intestinal canal, or its contents, as a focus of infection shows this difference from foci of the peridental and tonsillar varieties the bacterial activities in the intestine take place outside the wall of the body, while in the case of the other foci those activities take place inside the body wall. This difference, however, loses much of its significance when we consider the large field which the intestinal bacteria have to work in and the large extent of absorbing surface for their toxic products afforded by the intestinal mucosa, as well as the fact that abrasions in the intestinal mucosa are commonly present, through which bacteria can easily pass into the blood stream, and also the probable fact that in certain conditions they can penetrate mucous membrane which is structurally if not physiologically perfect

"A meat diet favors growth of the saprophytic or putrefactive types of bacteria, while on the other hand, a lactovegetarian diet, by favoring growth of the acidophilic types of bacteria and thereby change in the chemical reaction of the bowel contents, to a certain extent inhibits growth of the putrefactive types

"Matthews says (Physiological Chemistry, 1925)

"From the decomposition of proteins the most toxic substances are produced"

"Amino acids are inert, but bacteria can tear them to pieces, and some of the fragments are very toxic phenol and cresol may be set free, indol and scatol are produced by putrefactive action from tryptophane, cadaverin from lysin, hydrogen sulphide, which is capable of dissolving red blood cells from cystin, and the highly toxic

B-iminazolethylamin, hydroxethylamin and indolethylamin from histidin, tyrosin and tryptophane, respectively

"Amines of the ptomaine class produced by putrefactive bacteria have in many instances a powerful effect on the blood pressure, and may be of great importance in the production of high blood pressure and resulting thickening of the arterial walls"

"There can be no question of the importance of these putrefactive substances in the well-being of the individual

"None of the products of carbohydrate decomposition are harmful so far as known. By carbohydrate fermentation acidity is increased. Many bacteria cannot metabolize in the presence of acid

"Many hidden or chronic slight inflammations are often stimulated to become acute, or more active, by intestinal putrefaction. Thus colds may develop, catarrhs become worse, chronic nephritis of mild type becomes acute, erythemas develop in various parts of the body, or even old healed wounds with bad circulation may inflame and break out afresh

"Mackenzie says that intestinal toxemia is the most frequent cause of functional disorder of the heart

"Common clinical experience furnishes abundant examples of the bad effects of intestinal toxemia

"Nature, to a certain extent, provides protection against this focal infection, and the intestinal toxemia belonging to a mixed diet, which is man's proper diet, does little or no harm to healthy individuals. It is those who are below par or diseased who are vulnerable.

"But the number of such vulnerable individuals is so great that the treatment of this commonest focal infection, which is essentially dietetic, occupies a prominent place in therapeutics"

## WEEKLY HEALTH MESSAGES IN IOWA

The *Journal of the Iowa State Medical Society* for February contains an article on Weekly Health Messages, from which the following abstracts are taken—THE EDITOR

"In order that the general public may become properly informed in regard to the better methods of preventing disease, it is necessary to carry on a continuous campaign publicity. This may be done by state or local boards of health by themselves, by the medical societies as such, or by a co-operative effort on the part of various organizations

"The State Department of Health is now issuing a Weekly Health Message of about 250 words dealing with some timely subject and accompanied by morbidity statistics of communicable diseases. These are being sent to newspapers and other publications, to health officers of the larger cities, and to the president and secretary of every county medical society

"It is being sent to the officers of county medical societies for two reasons

"1 That the medical profession may be kept

informed regarding what is being sent out by its State Health Department

"2 To encourage the proper local organizations to make use of such or similar material as may be proper and appropriate for local publicity purposes"

"Messages" issued to date are as follows

No 1 December 6—"The Prevention of Scarlet Fever by Immunization"

No 2 December 13—"Closing of Schools Because of an Outbreak of Communicable Disease"

No 3 December 20—"Goiter in Iowa"

No 4 December 27—"Rabies Eradication Through the Protective Inoculation of Dogs"

No 5 January 3—"January Wave of 'Colds' Can be Stopped"

No 6 January 10—"Reducing the Infant Death Rate"

No 7 January 17—"Measles"

## RE-INFECTION WITH SYPHILIS

The *Long Island Medical Journal* for April contains the following report of a case of second infection with syphilis, written by Dr Henry H Morton, of the Long Island College Hospital

"Before the discovery of the Wassermann test and its application to practical purposes of the diagnosis of syphilis, it was universally taught that one attack of syphilis conferred immunity against the disease during the patient's lifetime. A probable explanation of this fallacy would be that many individuals who showed no outward signs of the disease, were actually still syphilitic and would have shown a positive reaction of the blood if they had been put to the test. Attempts at inoculation of syphilitic individuals with virus from another syphilitic always failed, except in the first three or four weeks after infection (super infection) as has often been demonstrated by laboratory experiments particularly on animals. As soon however as the syphilitic is cured, and the Wassermann reaction of the blood and spinal fluid are again negative, the state of immunity no longer exists and the patient is susceptible to inoculation with *spirochaeta pallida*, the syphilis develops and runs its usual course. A few cases of true second infections of syphilis are on record, and with proper care the initial sore in such a case may be easily differentiated from a tertiary gumma developing long after infection on the site of the original chancre.

"The following case illustrates a true second infection with syphilis in an individual who had previously had syphilis and was cured. The patient, a male, twenty-six years of age, consulted me October 31, 1921, on account of a hard papule on the prepuce which had been present for fourteen days and had appeared about one month after a suspicious coitus, darkfield

**NICHOLS**  
**NASAL SYPHON**

was positive for *spirochaeta*. Intravenous treatment was begun at once, and in six weeks the patient received 3.6-10 grams of old salvarsan followed by twelve injections of salicylate of mercury. On April 10th the blood Wassermann was negative and remained so, the blood being taken at intervals, the last one being done on March 19, 1924. On March 24, 1924, he consulted me again, stating in the last six to eight weeks he had had coitus with three different girls, none of them prostitutes. On examination I found a round papule one-quarter inch in diameter with an ivory hard base, located in the sulcus-coronarius which he stated had been present for two weeks. On darkfield examination a few *spirochaetae* were found. Intravenous injections were begun at once and the patient received in all, three grams of old salvarsan followed by twelve injections of salicylate mercury. The Wassermann was negative on beginning treatment and it remained so until the last examination on April 2, 1925.

"This case illustrates several points in the newer modes of thought in regard to syphilis

"1 One attack of syphilis does not produce a state of immunity in the patient, and an individual may acquire syphilis for the second time

"2 Syphilis may be entirely cured with one course of salvarsan and mercury if treatment is begun early enough

"3 It is most essential for the well-being of the patient to begin treatment as soon as the darkfield shows *spirochaetae* in the secretions from the initial sore.

"4 The chances of the patient for a cure with one course of treatment are better if treatment is begun while the Wassermann is still negative and before the virus becomes fixed in the tissues, when the Wassermann becomes positive

# NEW YORK STATE JOURNAL of MEDICINE

PUBLISHED BY THE MEDICAL SOCIETY OF THE STATE OF NEW YORK

VOL 27, No 11

NEW YORK, N Y

JUNE 1, 1927

## PRESIDENT'S ADDRESS

By GEORGE M FISHER, M D, UTICA, N Y

Delivered at the Annual Meeting of the Medical Society of the State of New York, May 11, 1927

ACCORDING to along established custom, it becomes my duty and privilege, as President of the Society, to address you this evening. In preparing the address, I found myself in the very unusual situation of having many subjects, the discussion of any one of which would be appropriate for this occasion. A few of those I think I should mention. There is the nursing situation. For several years we have had special committees make a study of the problem. They have offered a number of suggestions for the betterment of the situation, some of which have proven their value. There is no longer the acute shortage of qualified nurses which so seriously threatened proper care of the sick a few years ago, but the final solution of the problem has not yet been found, because all of the affected parties did not at once undertake jointly the solution of the problem, but now that selected committees representing the public, the physicians, the hospitals and the Department of Education, are giving the matter serious consideration, permanent relief can be expected.

The nurse's registry bill, which the legislature has just enacted into law, provides that registries shall furnish women sent out to do nursing with a card stating the qualifications and experience the bearer has had and the salary she is to be paid, and it also requires the agency to send the same information to the employer within twenty-four hours of the time of employment. Several benefits are likely to arise from this law, namely, unqualified women will find it difficult to misrepresent themselves, and those of less training will be prevented from asking the salary of a highly trained person. It will now be possible also for registries to supply patients with the type of nurse the case requires. We confidently believe the operation of this law will tend to relieve the shortage of nurses by helping the public secure with assurance the highest grade of trained nurse or one of moderate training, as it may require.

The etiology and effective treatment of cancer is another subject that is commanding international attention at the present time. Large sums of money are being appropriated today in almost

every civilized country for the construction and operations of hospitals, clinics and laboratories for the special study of cancer. This intense interest is warranted, because the vital statisticians advise us that the death rate from cancer is increasing. I may dispose of this subject by calling your attention to the program for tomorrow which will be devoted entirely to the consideration of cancer.

Another subject which, in one form or another, is commanding universal attention, is a provision for the compensation and rehabilitation of injured or incapacitated workmen. This subject has also received considerable attention by the committees appointed from this Society. Here, again, there are several parties concerned and no satisfactory solution to the problem can be expected until an equal interest is shown by all of those who will be affected. It is the hope of our committee that the legislature will see fit to reorganize the medical division of the Department of Labor along certain lines which they have been several years devising.

The need for physicians in the rural districts a problem which a few years ago was of such importance as to warrant the Governor calling a conference for its consideration has not been solved, on the contrary, observers tell us that there is still a marked movement of physicians toward the large centers of population. Another problem which, in some counties, is closely allied, is the construction and operation of hospitals in rural communities. The organization of a rural hospital system may effectively check the migration of physicians from the rural districts.

This seems to me to be an idea worth considering and a subject in which the public should take an active interest. Physicians are trained today to check up their diagnoses with various laboratory tests and neither the patient nor the physician is satisfied without recourse to such procedures. Equipment of laboratories for such tests is too expensive for most physicians to incorporate with their private offices and almost entirely prohibitive to the young man just beginning to practice. Therefore if rural communities want physicians

with modern training to settle among them some scheme must be devised by which these laboratory facilities will be immediately and locally available. Experience has proven that proper care for many conditions cannot be given in the private home. In such cases the patient is obliged to choose between limited care at home with the local physician, or hospitalization in a distant city under another physician. Good roads, automobiles and telephones are making the physician of the cities more available to residents of rural districts but they do not affect hospital and nursing care to the same favorable degree.

And another question which today is being widely discussed, not only in America, but in several of the European countries, is the part newspapers and magazines can take in the instruction of the public in medical matters. It has become an expected procedure for health officers and voluntary agencies interested in the promotion of public health programs, to use the press freely for the dissemination of such information as they desire the public to have. Their efforts in instructing the public have been so remarkable successful that articles on public health have been sought by certain publications, and at present we note in some an inclination to discuss truly medical problems that can only be treated properly by fully trained physicians. Physicians have hesitated to comply with the requests that are made upon them for such articles, on the ground that to sign them would be unethical, with the result that the public has manifested some impatience with our ethical restrictions. The British Medical Society recently expelled two of its members for having given to the public press medical articles over their own signature. The public press was divided with regard to the action of the Society, a majority disapproving.

Although there are other subjects in the medical realm of today that are demanding and receiving more or less interest, I shall invite your attention for a few moments to the consideration of what, in my opinion, is the most important activity man has ever undertaken, namely, the prevention of disease by the practice of preventive medicine. The old axioms that "At stitch in time saves nine" and "An ounce of prevention is worth a pound of cure," can be demonstrated nowhere more clearly or forcibly than by our present methods of protecting and promoting life. Disease and decay have always beset men and nations and master minds have ever been engaged in devising schemes for their prevention or postponement. Each generation contributes to the general advancement through its application of the principles and discoveries laid down by its scientists. One of our earliest records of an effort to prevent inroads of disease, is contained in the Laws of Moses, given to the children of Israel.

History records no more exciting nor fascinat-

ing events than the conquests of disease, and this is particularly true in recent years because lately man has been uniformly more successful in overthrowing his arch enemies than he had been in previous generations. The prevention of certain diseases is an actual accomplishment, and no longer a theory alone. However, much remains yet to be done. If this generation were to employ as completely as it should, the facts scientists have given us regarding the function and use of our bodies, the result would be truly miraculous. No other generation has employed in its own defense all of the facts that science revealed and therefore, it is safe to predict that this generation will not be markedly different unless some agencies not functioning in the past, should become active. For some unknown reason, the public has maintained an attitude of indifference, or only spasmodically shown any interest in the promotion of programs of health. When the public has been thoroughly aroused to the importance of some health procedure, they have demonstrated what wholehearted cooperation can do. This has been beautifully illustrated in many cities and countries in the efforts made to secure pure drinking water and the disposal of waste. Fifty years ago this Society had a very active committee on hygiene, whose annual reports abounded in elaborate and scientific surveys of water supplies, various members of the committee reporting upon the water supply of their own city or county in their district.

The knowledge that polluted water is dangerous to human life, was known and spoken about by physicians for a good many years before the public became interested, but after several severe epidemics of cholera has visited some of the large cities and the relation of the epidemic to the water supply definitely established, the public everywhere made the purification of its supply of drinking water its principal concern. Large sums of money were appropriated and the most capable physicians and engineers employed to provide supplies of pure water.

When citizens of New York City began to be skeptical about the healthfulness of milk produced by cows stabled in breweries and fed on swill, the Mayor invited the Academy of Medicine to make a study of the subject and report to him upon it. The report this committee submitted in 1858 condemning the use of milk so produced, was one of the earliest reports on milk in United States. This report stimulated public interest in its milk supply, which has progressed until today, when the milk distributed even to the smallest community is subject to inspection by State officials and must meet the requirements laid down by the law. There is no rumor that can produce a more spontaneous uprising of the people than to have them learn that their milk is being diluted or contaminated. By thus safeguarding these two food supplies, the public has

added a least decade to the lives of the present generation

If further examples are needed to prove the point that I am attempting to make, that when the public is interested to the point of cooperating with physicians, the discoveries of scientists can be made practicable and prove valuable, I would call your attention to the exceedingly few cases of smallpox reported annually now, as compared with the violent epidemics that swept the country fifty years ago, or to the results that have been achieved in rescuing the people from the dread disease of tuberculosis. This campaign has not yet been concluded, but if the public maintains its interest and cooperates not only by appropriation of sums of money, but with observance of sanitary regulations, victory is assured.

It is evident, therefore, that prevention of disease and postponement of decay will vary in direct proportion to the degree of cooperation between physicians and public. Many physicians and philanthropists and public spirited men have always been aware of this relationship, but it has not always been possible to agree upon programs of cooperation and some splendid plans have miscarried because of mutual mistrust in the sincerity of individuals engaged in their development. The mystery of life and death is such an excellent base for superstition that it is always difficult to free everybody from some extravagant or pessimistic thinking and base all plans for advancement and deductions of success upon observed facts and actual findings. We physicians must admit a share of responsibility for the failures in the past, because our societies, both county and state, have too frequently put an indifferent interest in the public efforts that were made. During the past year we have made an effort to insure complete medical cooperation in future health protecting programs, by naming a number of experienced physicians from the State Society to compose a committee on Public Relations, and this committee in its reports recommends that each County Society create a similar committee. The committee of the State Society began functioning immediately by considering with representatives of the State Charities Aid Association the medical phase of activities it is promoting. The committees have had several conferences, the minutes of which have been published in the JOURNAL. They have come into entire agreement upon the following points:

- 1 That mutually confidential relationship which has always existed between patient and physician is ideal and must not be disturbed or abandoned, but promoted

- 2 The indigent must be protected against communicable disease, and when infected, so isolated and treated as to afford the public the greatest degree of protection

- 3 Voluntary agencies can do a great work by

stimulating a constructive interest in the public in behalf of its welfare

- 4 The County Medical Society should be in intimate contact with all activities that concern the health of the public or its individuals, and offer its advice and assistance when its special knowledge and experience would be of value

It is the intention of the Society that this committee shall have similar conferences with the representatives of the State Department of Health, and all other associations engaging in activities allied to medicine. These conferences should result in clearing away most of the misunderstanding that now is interfering with the harmonious extension of the benefits of modern medicine and medical training. In proof of this contention, let me cite the campaign that is being waged against diphtheria. This dreadful disease has been the enemy of childhood for centuries, and it is only within the last forty-five years that the germ causing the disease has been found. Knowing the germ, science has developed an antitoxin to counteract its poison, and lately a method of immunizing the child against the disease. In 1878, five years before the discovery of the diphtheria germ by Klebs, Dr. Francis Stuart of Brooklyn reported to the State Society at its annual meeting that in that city of half a million population, "There was an average of 20½ deaths weekly from scarlet fever and twice as many from diphtheria during the first three quarters of the preceding year." He added that there was no epidemic of the diseases in that time and that the number of deaths from both diseases increased in the last quarter beginning shortly after the opening the schools. Brooklyn was losing annually more than 3,000 children from these two diseases. Dr. Janeway, the next year reported that in New York City, with a population of one million, 1,000 children had died from croup and diphtheria during the first three quarters of the year. In 1875 and 1876, the cities had been visited with an epidemic and the reports of the committee on hygiene for those two years state that in the first three quarters of each year there were, in New York City, respectively 2,165 and 1,793 deaths from diphtheria. In 1926, in the entire State of New York, with a population 12 times as great as that of New York City in 1878 there was reported only 728 deaths from diphtheria. This wonderfully successful campaign against diphtheria is not completed, but except for the possibility of local brief epidemics where immunization may not be completed or may have been neglected, we shall never again feel its destructive power, because this is a disease that can be prevented and the public and physicians have permanently combined for its elimination and prevention.

The employment of methods of prevention have also been successful against certain other common infections which were accustomed to

sweep the country in violent epidemics. Typhoid fever, the dreadful scourge in times of peace and war, always killing more than the bullets, was almost entirely eliminated from the world war after the first year. Yellow fever, cholera and malaria, the scourges of the tropics which were even known to visit our State in its early history, are fast receding before effective methods of prevention employed against them.

Practice of preventive medicine does not mean solely preventing the inroads of contagious diseases, but embraces, also, methods of preventing and postponing the advance of degenerative diseases and conditions. When men will realize that the onset of degenerative diseases may be postponed as effectively as communicable diseases can be prevented and physicians will take the same interest and pains to discover and control them, the expectancy of life will again be markedly increased. I greatly regret that in my travels over the State in the last year, I found so little evidence of the physicians incorporating as a definite part of their practice the periodic examination of adults. Pediatricians are developing their specialty in this field to the point where many no longer wish to see the sick, but are devoting their entire time to advising with parents as to the proper methods of protecting and developing their growing children. There is an equal opportunity for the general practitioner to advise with his adults if he will only realize it. I am inclined to think we are making too much of an excuse of the fact that only a specialist can give advice. I am not in accord with this spirit. The general practitioner makes many diagnoses of ills and ailments and treats all but a very few without the assistance of a specialist, and if he is capable of doing that, he is certainly capable of examining individuals at intervals and advising him how to live so as not to do himself an injury, or to tell him when to see a specialist about a condition that he may discover and for which he may not care to take full responsibility. The public is learning from many sources the value of an annual inventory of health, and I confess I grow impatient with the physicians' indifference to this developing demand.

Annually we are obliged to go to Albany to oppose bills introduced by cults of one type or another. Have you ever wondered why the Legislators should be willing to spend their time on such stuff? I'll tell you something about it—the cultist, having no great store of medical knowledge, does understand human nature and he takes pains to convince his clients that he is interested in their welfare. They appreciate his efforts and besiege the legislators in his behalf. Do many patients of physicians show the same interest in the physicians' welfare? Are we not, through our great specialization, losing the interest of our patients? Are we not growing to be more interested in our patient's head, heart, lungs or some other specific

part or organ, rather than in the patient as the possessor? Not only do we no longer take the interest in our patients that the physicians of the previous generation took, but we are inclined to take little or no interest in health of the public as such. How many times have I heard physicians reply to questions of public health, that they knew nothing of them—the health officer was employed to look after such. Should not the activities of the health officer be a concern of every physician practicing in that community? We hear criticism of the public clinic, but how many physicians have given the cause enough consideration to be able to suggest a plan to take the place of the public clinic system? Physicians are losing patients daily to public clinics, all through their own indifference. Physicians employed by industries find it exceedingly difficult to confine their work to their plants because the employees think the man who gives them, periodically, an examination and advice, is more approachable than the physician outside. It is a very serious matter in the care of the sick when the family physician cannot command the full confidence of the family, and it is absolutely impossible to practice preventive medicine under such conditions.

Physicians' ethics do not permit them to advertise, but they are not prevented from taking advantage of the instruction given by others, whether through public lectures or printed page. I urge again that we all take a lesson from the pediatricians and develop a practice of keeping the well person robust, rather than limit ourselves to the troublesome ill. We shall find it more profitable and less nerve racking.

In this connection, let me speak of the latest action of the State Society in the field of preventive medicine. We have created a committee to study diseases of the heart. The findings of this committee should be impatiently expected by every practitioner in this State. No group of diseases is carrying off so many adults annually as the diseases of the heart and blood vessels. This committee should be able, from its findings, to give us suggestions as to how we may discover degeneration in the circulatory system early, and probably they can suggest some causes and remedies and precautions. I predict that they will recommend periodic examination of the hearts of all of the adults under our care. There can be no better advice, and if we follow it, we shall then be practicing preventive medicine in a field where it is greatly needed today. Medical men can do no greater work for humanity than to help make the diseases and degeneration of adults as well known and understood as they are of children today.

"Prevention" is the slogan of the day in medicine, and physicians were never better qualified to accomplish miracles in their practice than they are now. In our County Societies, in addition to scientific study, we should consider the problem

of health and hygiene in our communities and fit ourselves to be such leaders and directors as we are expected to be by those who desire to improve hygienic conditions or protect the public against the inroads of disease.

As your retiring President I am proud to say that the challenge has already been accepted. The Medical Society of the State of New York occupies today, through its members both individually and collectively, prominent positions in the forefront of every form of medical activity. Our advice and support is sought by the Governor of our State, by several departments of the State government, and by numerous voluntary agencies and

municipalities. We have merited this trust and confidence. It is therefore with mingled feelings of regret and pleasure that I reach the close of my term of office. The opportunities for unusual service were so plentiful and the hearty support I received from everyone was so cheerfully proffered that I shall ever look back upon this as the happiest year of my professional life. And it is with deep sense of satisfaction and confidence in the ability of your new President that I ask you to pledge him as valiant support as you gave me.

And thus another year will find the Society realizing more completely its unlimited opportunities and tremendous responsibilities.

## THORACIC SURGERY\*

By CARL EGGERS, M D, NEW YORK, N Y

THE Annual Meetings of the American Association for Thoracic Surgery have been an indication of the interest taken in this subject, and the transactions published in the Archives of Surgery each year are a record of the accomplishments during the preceding year, and are recommended to you for study. Progress in this field has been slow and continues to be slow, not because of lack of courage or ingenuity or skill on the part of surgeons, but because so many of the problems presented are different from those encountered in other surgical conditions of the body. We have to deal not only with surgical diseases that in themselves tax a surgeon's resources, but in trying to reach them the more intimate phases of respiration and circulation have to be considered, and ways and means found to avoid the dangers associated with disturbing them.

Whatever progress has been made has been due to the close collaboration between the Radiographer, the Endoscopist, the Medical man and the Surgeon. When surveying the entire subject one realizes how little we really know, and how much has to be learned. It is no wonder that many surgeons avoid thoracic cases. The treatment is usually long drawn out, the attention required frequently out of all proportion to the gain, and the results often discouraging.

Still a great deal has been learned, both in regard to diagnosis and treatment. One of the most important aids is the X-ray, and the full realization of its value has helped much to clear the conception of many hitherto misunderstood conditions. Endoscopy has advanced a great deal, so that we can now receive aid in diagnosis by means of the Bronchoscope and the Esophagoscope and in addition to that the instruments are used in the treatment of pulmonary suppuration and for the extraction of foreign bodies.

The greatest difficulty in thoracic surgery an acute pneumothorax, can now be effectually prevented by one or the other methods of differential pressure. Whereas in the beginning the apparatus for this purpose was complicated, beginning with Sauerbruch's negative chamber and Brauer's positive one, followed by Willy Meyer's combination of the two, and later by the Melzer-Auer method of intra-tracheal insufflation, we now have the simple so called intra-pharyngeal insufflation anesthesia. No special apparatus is required for this, but any of the well known gas-oxygen-ether machines answer the purpose. Every institution may therefore fearlessly attack any interference with either their respiratory or a snugly fitting mask one may vary the intrapulmonary pressure by increasing or decreasing the pressure in the bag, and the lungs may be kept moderately inflated or completely expanded as desired. The alternating collapse and expansion is at the same time a wonderful stimulant for the heart, and may be resorted to at intervals in all long drawn out operations, or when shock is threatened.

Another thing we have learned is the great value of doing thoracic operations under local anesthesia, thus avoiding irritating the lungs in a system already affected. Resection of the chest-wall, operations for acute empyema and lung abscess, also many chronic empyema cases and operations for extra pleural collapse in bronchiectasis and tuberculosis may well be done under local anesthesia. Then also we have learned much about prophylaxis, what not to do under general anesthesia thus avoiding aspiration of septic material. In case aspiration has taken place an early bronchoscopy, sucking out the offending material, may prevent dreaded complications.

In deciding on operation for any intra-thoracic lesion the general condition of the patient has to be carefully considered, to determine in advance

\* Read before the Nassau County Medical Society November 10 1926

about how much he can stand, and not to overtax his resistance. In a practical way the importance of this has been recognized for a long time, and out of it have developed methods of procedure dividing operations into several stages, avoiding large defects in the thoracic wall, avoiding opening the chest in cases of empyema while the pneumonia is still active, instituting closed rather than open drainage in certain cases, etc. Scientifically speaking, one calls this taking the vital capacity of the patient into consideration. By vital capacity is meant the total amount of air a patient can inhale with a maximum effort. Normally it is about 8-10 times as large as the amount of total air used in ordinary respirations. It varies a great deal in different individuals and in the same individual under different conditions of rest, exertion, emotion, etc. Medical and surgical conditions of the respiratory and circulatory system and allied organs reduce the vital capacity until in some patients with dyspnoea a maximum effort at inspiration is made with each breath. Such patients are evidently not able to withstand any interference with either their respiratory or circulatory mechanism. Vital capacity depends on the normal functioning of circulation and respiration, and varying degrees of disturbance give varying degrees of reduction of this function. In the same way, opening the thorax at once reduces the vital capacity, and the amount of reduction depends on the size of the opening, the mobility of the mediastinum and the amount of interference with the intrathoracic organs, and it is therefore important to take all these into consideration.

When we come to consider the various affections of the thorax and its contained organs, we find that in the treatment of some very little progress has been made, while in others results are shown which stimulate us to further efforts.

#### CHEST WALL

Surgical affections of the chest wall have always been attacked by the general surgeon, and no special apparatus is required so long as the parietal pleura is not involved and does not have to be opened. Even the most extensive may be operated on under local anesthesia. One should be prepared, however, to use intrapharyngeal insufflation anesthesia in case the pleura is found to be involved. A combination of the two is often advantageous. If it is known in advance that the pleura is involved, it is best to begin the operation under general anesthesia, because patients do not stand wide opening of the thorax under local well. Cold abscesses, tuberculosis of the rib, gummata, osteomyelitis and chondritis may all be operated on with the aid of novocaine, because the underlying pleura has usually become so thickened that there is no danger of entering it.

The principal tumors that come under consideration are sarcomata and chondromata. They are quite malignant, but fortunately are relatively rare. The ribs are much more often affected than the sternum, being twice or three times more common. Radical removal is the operation of choice, but if that is not possible, a palliative procedure, consisting of partial destruction of the tumor by means of the cautery, is of value. It may prolong life and relieve the distressing pain of which these patients complain. Secondary carcinoma of the chest-wall, following amputation of the breast, is at times operable and its removal may lead to complete cure. In the absence of metastases elsewhere an attempt at radical removal should therefore be made.

#### EMPYEMA

Many consider this a closed chapter, and although there is nothing new to offer in this field, it behooves us to take stock and see whether we cannot improve on our results. Empyema is a common disease, frequently with a very high mortality, and it is therefore of great importance to the community. For this reason steps taken to combat its mortality are really of great immediate value. Then also so many young people are afflicted, whose lives should be saved, that it becomes necessary for every surgeon to familiarize himself thoroughly with all the aspects of empyema. One of the most interesting things in connection with this condition is the wide variety of mortality statistics, ranging from 1 to 25 or more per cent. I do not mean the statistics of an epidemic, which are nearly always high, but those sporadic cases which occur over a period of years in the usual hospital service, and are collected by different authors. Although it is known that the type of organism is an important factor one is also forced to the conclusion that the method of treatment plays an important role. In considering treatment it is not only a question of the type of operation, whether one uses rib resection or intercostal drainage, closed or open treatment, but whether the operation was done after preliminary aspiration and whether the pneumonia had subsided at the time. There is no doubt that all these points are of the greatest importance and that attention to them determines to a large degree the outcome in a given case. Each patient must be carefully studied and an operation done in such a way and at such time, as will most likely restore him to health. There is no need to consider such cases emergencies except in a very few instances.

For practical purposes it is well to differentiate between pneumococcus cases and those due to the streptococcus, staphylococcus or colon bacillus, for in the former one is more likely to have thick pus early, and in the latter group thin pus and in larger quantities. Of course this is not an absolute finding, but it guides one some-

what If no laboratory is available, and one is in doubt which organism one is dealing with, a practical guide in treatment should be

1 To delay operation until the pneumonia has subsided

2 Not to evacuate an extensive pleuritic exudate suddenly

Applying this to an individual case it would mean the following

In a patient with a small or moderately large empyema, in whom the pneumonia has subsided and the exudate is thick creamy like, showing about 50% pus by sedimentation, the best operation is resection of a portion of rib, usually the 8th or 9th, or in case of a localized pocket, of a piece of that rib which will most likely insure good dependent drainage

In a patient with an extensive exudate of thin pus, which may interfere with respiration and circulation and in whom the heart is grossly displaced, it is best to do one or more preliminary aspirations by means of a Potain Aspirator, or if that does not work well on account of flakes of fibrin constantly blocking the needle, to institute some form of closed drainage. The purpose of this is to carry the patient along until the pneumonia has subsided and sufficient adhesions have formed to avoid the dangers of an acute open pneumothorax. Later one may safely resect a rib and continue open drainage. The simplest way to perform a closed drainage is to insert a straight trocar in the 8th or 9th intercostal space and then slip a rubber tube through this into the thorax sufficiently far to have the openings of the tube just within the thoracic wall. The tube is then connected with a drainage bottle with the end of the tube under fluid level

With intelligent treatment the majority of acute empyema cases heal in from 3 to 6 weeks. It is important to follow the case by means of the X-ray to detect secondary pockets or a possible underlying lung abscess. The chief consideration is to maintain good drainage, because imperfect or inadequate drainage is the principal factor in producing chronicity. If this is generally known and properly appreciated chronic empyema should come under our care less frequently

What should we do with a chronic case, however when it does come under our care? It should first of all be studied carefully to determine why it has not healed. A good history, examination, cultures and X-ray will help to do this. After this one should establish good drainage at the dependent part and then begin the use of Dakin-Carrell treatment. The latter is of great value in this class of cases, as it tends to sterilize the cavity and the latter then quickly diminishes in size and either heals or is put into better condition for subsequent operative interference. In addition to treatment, however, these

patients must be given exercise, sunlight and a diet high in caloric value

If all these measures fail to bring about healing, an operation is indicated for the removal of whatever factor is responsible for the chronicity. It may be an osteomyelitis, secondary pockets, a rigid unyielding cavity, an infected lining, foreign bodies or one of several others. If the cases are properly prepared and the best time for operation chosen the results, both immediate and late are very good. The important thing is not to do too much in one sitting, but rather divide the operation into two or more stages

#### INTRAPULMONARY SUPPURATION

This entire chapter is a difficult one for several reasons. The patients are usually very sick and have little resistance. There is considerable difficulty in making a correct diagnosis of the nature of the process, and of its exact location and extent. Then, too, there is still a great deal of confusion regarding the best way to treat these suppurations. Of this chapter of thoracic surgery one may truly say progress is being made, and the bronchoscopists deserve a great deal of credit for this. We all know that acute abscess may clear up spontaneously, and that therefore, one should be conservative in the beginning. A cure may be hastened by postural treatment. If the location is favorable, they may be cured by bronchoscopic treatment, evacuating the pus and perhaps instilling some antiseptic solution. Some abscesses perforate into the pleura, and drainage of the resulting empyema will bring about a cure. Others have to be operated on. There is still no unanimity of opinion regarding the best time to operate. Some surgeons incline to a very early operation, while others prefer to wait until the acute signs and symptoms have subsided. There seems little doubt that early operation will insure a more perfect restitution to normal, and that late operations are more often followed by a bronchial fistula and by permanent damage to the affected lobe. On the other hand, the operations done during the acute septic stage have a much higher mortality. The decision is therefore, always a serious one and I believe that unless the abscess has been localized very definitely and is easily accessible, it is wiser to delay operation until a more opportune time. One may operate in one or two stages. The purpose of the two stage operation is to bring about adhesions of the affected portion of lung to the parietal pleura. This is accomplished by painting with tinct of iodine by a circular suture or by packing gauze against the parietal pleura. Another reason for a two stage operation is not to overtax the strength of the patient whose vital capacity is usually low. Occasionally, however, the entire procedure can be carried out in one stage. The functional and

cosmetic results following operation are very good

*Chronic Lung Abscess*, or bronchiectatic abscess is the result of an acute abscess and has been deliberately carried over into this stage, or it has not been diagnosed until the chronic stage was reached. Unless bronchoscopic treatment shows definite results, operation is indicated. The main cavity is usually sufficiently large and well outlined to be located fairly definitely by means of the X-ray. There is, as a rule, no septic state and operation is therefore well borne. It is carried out under local anesthesia. One resects one or more ribs as indicated, removes the intercostal structures, and then enters the cavity either by means of a knife or a cautery. The cavity is laid wide open and drained, and the edges may be sutured to the skin in order to establish permanent drainage by means of a so-called lung-lip fistula. The continuous aeration brought about in this manner does away with all odor, expectoration stops almost immediately, and the discharge from the wound rapidly diminishes until there is just a slight amount of mucus requiring a dressing every one or two days. Although the condition is not an ideal one, the patients are to all intents and purposes well, and they gain in weight rapidly. As the old cavity is lined with epithelium and communicates with one or more bronchi, it has difficulty in obliterating itself. Only the small ones eventually close, while the larger remain permanently unless they are closed by operation.

*Bronchiectasis* is still the most difficult suppurative pulmonary condition to treat, and the results of operative treatment are not encouraging. Complete extirpation would be the operation of choice were it not for the exceedingly high mortality. Its application is in those patients in whom only one lobe is involved, but unfortunately both lobes are frequently affected or the disease is bilateral in character. Extra-pleural thoracoplasty done in one or several stages is applicable to those cases in which only one side is involved. Though it does not cure, it renders life much more bearable to those unfortunates. Cautery lobectomy is of late being praised as a curative agent and very good results have been reported, but hemorrhage and embolism are two complications which have to be reckoned with.

It has repeatedly been observed that bronchiectasis may begin as a localized disease in one lobe, and secondarily involves the other lobes. The early recognition of the disease therefore and treatment instituted at that time, either drainage or cautery lobectomy or complete extirpation, would offer the best chance for cure.

Suppurative processes are occasionally encountered in the mediastinum. They may be successfully attacked by way of the neck or from behind. It has been shown that even suppurations

extending quite far down can be successfully drained from above, and as this approach is the easier one, it should be the one of choice. At any rate, an attempt should be made to save these patients and not to abandon them to their fate.

#### PULMONARY TUBERCULOSIS

Tuberculosis in some of its phases is gradually being looked upon as a surgical disease, and the reports of the men who have done most in this field are quite encouraging. The thought underlying all these operations is to put the lung at rest. This may be accomplished in several ways, by artificial pneumothorax, by phrenicotomy, or phrenectomy, by apicolysis, or by extrapleural thoracoplasty.

Artificial pneumothorax is a procedure carried out by the medical men. It is indicated in about 10-15 per cent of all tuberculous cases, and should be resorted to in all patients in whom there has been no improvement with the usual medical treatment after about six months. It is chiefly of value in moderately advanced cases, and in those in which cavity formation is developing. It controls hemorrhage, diminishes toxæmia, and arrests the progress of the disease.

Phrenicotomy may be done as a preliminary to thoracoplasty or in conjunction with pneumothorax in order to put the diaphragm at rest. It is carried out under local anesthesia, and is a comparatively simple procedure. A small incision is made on the side of the neck, behind the sterno cleido mastoid parallel to the clavicle. The nerve is isolated behind the large vessels lying on the scalenus anticus, and is then resected or avulsed. There is some difference of opinion regarding the value of this measure alone, but in conjunction with thoracoplasty it completely puts the lung at rest. Apicolysis is not used much, and is at times a dangerous operation. The object is to bring about collapse of an apical cavity.

Extra-pleural thoracoplasty is done under local or gas oxygen anesthesia, or a combination of the two. It may be done in one or two stages. Short pieces of the tenth to the first rib are removed. Most writers report from 20-30 per cent cures and improvement in many others, surely a most encouraging outlook. With the new rule in force in this state, permitting the admission of patients with pulmonary tuberculosis for operation to the wards of general hospitals, it is hoped that it may be possible to help many unfortunates who are unable to avail themselves of sanatorium treatment. The indications for operation are gradually being extended, and whereas in the beginning only advanced cases were operated on, as a last resort, so to speak, it is being recognized that the best results are obtained in earlier cases. The proper selection of patients is of course, carried out with the assistance of experts in tuberculosis, for it is of the greatest importance to choose the proper time for opera-

tion and to carry out the various steps of surgical intervention in such a way as will most likely bring about a good result

### TUMORS

Tumors within the thorax may arise in the pleura, the lung, or the mediastinum. Those most commonly observed are secondary to primary lesions elsewhere, and do not come into consideration. Primary tumors of the lung are usually malignant and take their origin in the bronchial mucosa or in the lung parenchyma. Fortunately, they are not common. Very little progress has been made in the treatment of these cases, chiefly due to the fact that the diagnosis was made late at a time when the surrounding vital structures had become involved. Nevertheless, several cases of successful removal are on record, and advanced cases have been relieved of distressing symptoms by a decompression operation or partial removal by means of the cautery.

Primary endothelioma of the pleura is likewise recognized late and is irremovable for that reason.

The use of the X-ray for diagnosis in all doubtful intrathoracic lesions cannot be urged too strongly, and it must be emphasized that exploratory thoracotomy should be resorted to more frequently. It is by these means that early diagnosis will be made and operability be found more often than is now the case. We do not hesitate to do an exploratory laparotomy in doubtful conditions, and why should not the same benefit be extended to patients with intrathoracic lesions? It is not right to resign patients to their fate until some effort has been made to save them. There are no standardized methods of procedure for these cases, each one has to be treated as seems best.

Under other intrathoracic tumors have to be considered lympho sarcoma, Hodgkins disease, adenitis of doubtful origin, dermoid cysts and goitre.

Lympho sarcoma arises in the mediastinum, is difficult to recognize and is usually so intimately connected with the surrounding structures that its removal is not possible. Decompression by splitting the sternum is the most that can be hoped for, perhaps combined with X-ray treatment.

Hodgkins disease responds beautifully to X-ray, and the pressure symptoms due to the presence of large nodes clear up promptly. The same is true of adenitis or granuloma of the mediastinum of doubtful origin.

Dermoid cysts, which reach a very large size have repeatedly been successfully operated on by extirpation, or by marsupialization with gradual obliteration.

Intrathoracic goitre can be successfully removed by operation under local anesthesia in order to have the cooperation of the patient.

To avoid unnecessary pressure on the trachea a vertical incision down to the sternum should be added to the usual transverse one. After bluntly freeing the tumor, which is sometimes quite difficult, it can finally be pulled out of the thorax during a swallowing effort.

### ESOPHAGUS

Operations on the esophagus are among the most difficult in surgery. All the benign affections of the esophagus are amenable to treatment. Strictures and cardiospasm are treated instrumentally, perhaps aided by a gastrostomy. Various plastic operations for reconstruction of an esophagus have been devised and successfully carried out. Idiopathic dilatations may be overcome by one of several plastic operations. Diverticulæ are successfully removed by the one-stage or two-stage method.

By far the most difficult and serious affection of the esophagus is carcinoma, for if left untreated, or if treated conservatively, or by means of radium or X-ray, the mortality is one hundred per cent. Surgery has a few successful cases to its credit. The operation is a difficult one, and many dangers attend it. There is usually considerable shock and acute pneumothorax, empyema, mediastinitis etc., have to be guarded against. There are two recognized methods of approach, one through the posterior mediastinum, which is extrapleural, the other transpleural. The latter gives better exposure and is, therefore at present, the method of choice. It is not possible to go into the details of all the various ingenious methods proposed and I will limit myself to the description of the technic proposed by Dr. Torek. It is in brief, as follows:

An incision is made along the entire seventh intercostal space and then upward posteriorly at the angle of the ribs over the seventh, sixth, fifth and fourth ribs. They are divided and the intercostal vessels ligated. The chest is thus laid wide open. The lung is pushed aside and the esophagus with the tumor dissected free. The esophagus is then divided below the tumor, and the lower end inverted into the stomach, while the upper end with the tumor is thoroughly freed behind the arch of the aorta and drawn upward. Through an incision in the neck, in front of the sterno-cleido mastoid, it is then pulled upward and delivered on the chest. After removing the tumor, the free upper end of the esophagus is transplanted under the skin bringing its open end to about the level of the second rib on the anterior thoracic wall.

The chest wall is then closed completely or with airtight drainage, as indicated in the particular case.

With earlier diagnosis there is reason to hope that it will become possible to save a fair proportion of these patients.

# THE RELATION OF UPPER AND LOWER RESPIRATORY TRACT DISEASES

By MORRIS E. NEWMAN, M.D., BUFFALO, N. Y.

IT is a very difficult problem to detail in a short paper the relation of diseases common in the nasopharynx and the associated sinuses to respiratory diseases, for they, in themselves form the first and one of the most important parts in the respiratory tract and derangement of either the anatomy or physiology of these parts has influence on the pathology of the respiratory system. The importance of studying these defensive arrangements and preserving them in full activity is emphasized by observations which show that most generalized diseases, especially in children, take origin from the respiratory tract, rather than from the intestinal, and these through the medium of the upper air passages.

The nose, being the first part of the respiratory tract, serves either as an aid to respiratory functions or as a hinderance. As an aid by its physiology, namely to receive the inspired air and by its mucous membrane to warm that air to near the body temperature. By its secretions to moisten it and in co-operation with the ciliated epithelium to filter out not only the dust in the inspired air but the incoming bacteria that are directed toward the larynx, trachea, bronchi and lungs. The strength of these lines of defense is shown by the arrest in the nares of various forms of bacteria as demonstrated by cultures giving various growths. Although they generally fail to infect their host, the organisms, trapped here, may retain their full virulence. The olfactory and sensory nerves of the nasal chambers assist in the defense of the organism by putting us on guard against evil smelling or irritating bodies, as demonstrated in the recent War by the detecting of gases which produced respiratory pathology.

There are many ways in which nasal pathology bears relation to the pathology in the balance of the respiratory tract, and for convenience and shortness I will subdivide them into congenital and acquired. Among the congenital, the most important is atresia of the nares, which prevents all breathing through normal channels and makes patient a compulsory mouth breather. Under the heading of acquired we have acute and chronic inflammations and deformities. Under the acute we include the common cold or rhinitis, which is an inflammation of the mucous membrane of the nares with swelling and secretion and if not impeded, travels by the ciliated epithelium to the rest of the respiratory tract. Diphtheritic infection most frequently has its origin in the nose and many cases of so-called cured diphtheria still act as carriers, by harboring the organisms in its passages. The same can be said of the other general infections principally influenza, measles and scarlet fever.

Of the chronic inflammations the two giving us most concern are firstly tuberculosis and sec-

ondary syphilis. Tuberculosis involving the respiratory channels, which is the most common type, takes origin in the intake of infected air. Those cases of good resistance and good nasal physiology escape deeper involvement but in performing its function these organisms sometimes are virulent enough to set up a local tuberculosis in the nose, involving cartilage and mucous membrane. This local involvement may be carried downward at a distant time to the bronchi and lungs.

Syphilis manifests itself by bone destruction, commonly seen in the saddle nose or luetic ulcers. This inflammation is probably a secondary involvement.

Deformities play an important part in the functions of respiration. The most common is a deflected septum which by its deflection presses on the turbinates to the side of the convexity and nature, trying to close in the large space on the concave side, produces a compensatory hyperplasia and hypertrophy, resulting in obstruction to the incoming air and preventing the normal physiology to be performed so that the normal warmed and washed air fails to reach the lungs for interchange of carbon-dioxide for oxygen. The obstruction prevents the normal secretions from exuding and causes them to trickle down to the nasopharynx and larynx. The sinuses are not properly aerated and their secretions are retained which later may become infected and set up a sinusitis. The obliteration of the olfactory fissure causes exaggerated efforts at inspiration and consequent deformities of chest and spine. Other deformities in the nose producing identical symptoms as above, are chronic hypertrophic turbinates, polyps, new growths and foreign bodies.

The accessory sinuses are namely the frontal, sphenoid, maxillary, anterior, posterior and anterior ethmoids. These are normal cavities in the skull, lined with mucous membrane and each emptying by their respect openings into the nasal chamber. Their function is believed to lighten the skull, warm the air, aid in phonation and maybe, the production of a bactericidal secretion. Due to their proximity to the nares and the predominance of many nasal deformities, these air spaces are frequently infected and many go on to a stage of chronicity and as such are frequently the etiology of unexplained cough, acute and chronic laryngitis, chronic bronchorrhea, asthmatic attacks and recurrent outbreaks of broncho-pneumonia simulating pulmonary tuberculosis. Darling in 1909 proved, by a series of post-mortem examinations, that in a series of pneumonia cases the portal of entry was mostly an accessory nasal sinus. The writer would like to report two cases out of many cases illustrating these points. One a man with complaint of headaches, bad taste in the mouth and tickling sensation in the throat. Cocainization

and suction produced a tablespoonful of old pus from the frontal sinus. After a few suction treatments the patient reported as being greatly relieved. The other an adult woman, who had a chronic cough for many months, which various cough mixtures failed to relieve. Examination of accessory sinuses revealed a right antrum filled with pus and a posterior ethmoiditis. Removal of the sinus infection has stopped her cough.

Lack of space necessitates the writer to enumerate the conditions present in the nasopharynx. Of prime importance we name adenoid growths, which is a noncryptic lymphatic tissue, located in the posterior nares, and enlargement of same gives symptoms as per nasal obstruction. New growths are sometimes seen and the writer mentions two cases seen abroad. One a young boy, age 17, with a fibroma in nasopharynx which increased in size and came through the sphenopalatine canal and grew to an enormous size on the left side of face. The other an angioma which looked like an ordinary nasal polyp, flopped back in nasopharynx. The boy came in for difficulty in breathing and pretty near went out without breathing, for when a snare was applied and closed the spurting blood looked like a river. Many cases of carcinoma and sarcoma from the spine are reported.

In the pharynx we have the associated masses of lymphatic tissue, known as Waldenstrom's Ring, comprising the group termed tonsils. The palatine tonsils are masses of tissue between the anterior and posterior palatine muscles, surrounded by a capsule and frequently cryptic. Their exact function is unknown but many believe that, they in their uninfected state, act as a filter to organisms on their way to the respiratory tract. The presence of enlarged tonsils so commonly seen in children, prevent proper air currents from reaching the larynx producing inadequate hematosis.

Tuberculosis frequently selects the tonsils but whether this is a primary involvement by the organisms stopping there first, and then inhaled into the lungs or whether they lodge there later from the expectorations can not be said. Lues frequents this area and is mostly seen as the primary lesion due to unnatural practices or as the ulcerations of the mucous patch. Gummatous growths are reported and many cases of carcinoma of tonsils and adnexa are on record. Among the acute infections we mention acute tonsillar and retropharyngeal abscess, Vincent's angina, mycosis and glossitis. The lingual tonsils are masses of similar lymphatic tissue seated near the base of the tongue and cause pathology in the tracts below by their hypertrophy.

No paper on respiratory diseases would be complete without attention to the larynx. Among the acute inflammations are mentioned acute laryngitis, oedema, spasmodic laryngitis, diphtheria and among the chronic are congenital glottic stenosis, chronic laryngitis, laryngitis sicca, singers nodules, hypertrophic laryngitis, pachydermia laryngis and new growths. The benign common ones being papilloma, fibroma, lipoma and adenoma. The malignant are classified as to intrinsic, extrinsic and mixed, and are the same as malignant growths elsewhere.

#### Conclusion

It is clearly demonstrated that there is a distinct correlation between pathology present in the lower respiratory tract as influenced by conditions present in the upper tract. This bears importance in considering treatment, as seeking the focus and treating that alone, may clear up the distant pathology. It is the author's purpose to bring forward these various distant upper tract conditions as an important addition to lower respiratory tract diagnosis and treatments.

## UNUSUAL SHORT HISTORY IN PENETRATING GASTRIC ULCER—REPORT OF TWO CASES\*

By HENRY A. RAISKY, M.D., NEW YORK, N. Y.

**A** PENETRATING gastric ulcer is one which erodes one or more coats of the stomach wall with the formation of a pouch-like bag on the edge of the stomach. This pouch is frequently surrounded by inflammatory tissue. Before the advent of the roentgen ray many of these lesions were not recognized unless they were discovered at the operating table or at post-mortem. Recently, however, Einhorn,<sup>1,2</sup> Cole,<sup>3</sup> and others have shown how easily these cases can be diagnosed by the use of the X-ray.

The usual conception of a benign penetrating gastric ulcer has been that it must be preceded by a long train of digestive disturbances varying

from one or more months to several years. It has always been taken for granted that these lesions are chronic affections with acute exacerbations, occurring from time to time in the life cycle of the ulcer.

The history of an ulcer patient is of the utmost diagnostic value and is our sole guide as to the duration of the lesion. Penetrating ulcers of short duration without a previous gastric history are rare. After a thorough search of the literature I have been unable to find the report of one case of a penetrating gastric ulcer with a history of shorter duration than one month. Therefore, I thought it would be of interest to report two cases of penetrating gastric ulcer where the history of one was ten days' duration and history of

# THE RELATION OF UPPER AND LOWER RESPIRATORY TRACT DISEASES

By MORRIS E. NEWMAN, M.D., BUFFALO, N. Y.

IT is a very difficult problem to detail in a short paper the relation of diseases common in the nasopharynx and the associated sinuses to respiratory diseases, for they, in themselves form the first and one of the most important parts in the respiratory tract and derangement of either the anatomy or physiology of these parts has influence on the pathology of the respiratory system. The importance of studying these defensive arrangements and preserving them in full activity is emphasized by observations which show that most generalized diseases, especially in children, take origin from the respiratory tract, rather than from the intestinal, and these through the medium of the upper air passages.

The nose, being the first part of the respiratory tract, serves either as an aid to respiratory functions or as a hinderance. As an aid by its physiology, namely to receive the inspired air and by its mucous membrane to warm that air to near the body temperature. By its secretions to moisten it and in co-operation with the ciliated epithelium to filter out not only the dust in the inspired air but the incoming bacteria that are directed toward the larynx, trachea, bronchi and lungs. The strength of these lines of defense is shown by the arrest in the nares of various forms of bacteria as demonstrated by cultures giving various growths. Although they generally fail to infect their host, the organisms, trapped here, may retain their full virulence. The olfactory and sensory nerves of the nasal chambers assist in the defense of the organism by putting us on guard against evil smelling or irritating bodies as demonstrated in the recent War by the detecting of gases which produced respiratory pathology.

There are many ways in which nasal pathology bears relation to the pathology in the balance of the respiratory tract, and for convenience and shortness I will subdivide them into congenital and acquired. Among the congenital, the most important is atresia of the nares, which prevents all breathing through normal channels and makes patient a compulsory mouth breather. Under the heading of acquired we have acute and chronic inflammations and deformities. Under the acute we include the common cold or rhinitis, which is an inflammation of the mucous membrane of the nares with swelling and secretion and if not impeded, travels by the ciliated epithelium to the rest of the respiratory tract. Diphtheritic infection most frequently has its origin in the nose and many cases of so-called cured diphtheria still act as carriers, by harboring the organisms in its passages. The same can be said of the other general infections principally influenza, measles and scarlet fever.

Of the chronic inflammations the two giving us most concern are firstly tuberculosis and sec-

ondary syphilis. Tuberculosis involving the respiratory channels, which is the most common type, takes origin in the intake of infected air. Those cases of good resistance and good nasal physiology escape deeper involvement but in performing its function these organisms sometimes are virulent enough to set up a local tuberculosis in the nose, involving cartilage and mucous membrane. This local involvement may be carried downward at a distant time to the bronchi and lungs.

Syphilis manifests itself by bone destruction, commonly seen in the saddle nose or luetic ulcers. This inflammation is probably a secondary involvement.

Deformities play an important part in the functions of respiration. The most common is a deflected septum which by its deflection presses on the turbinates to the side of the convexity and nature, trying to close in the large space on the concave side, produces a compensatory hyperplasia and hypertrophy, resulting in obstruction to the incoming air and preventing the normal physiology to be performed so that the normal warmed and washed air fails to reach the lungs for interchange of carbon-dioxide for oxygen. The obstruction prevents the normal secretions from exuding and causes them to trickle down to the nasopharynx and larynx. The sinuses are not properly aerated and their secretions are retained which later may become infected and set up a sinusitis. The obliteration of the olfactory fissure causes exaggerated efforts at inspiration and consequent deformities of chest and spine. Other deformities in the nose producing identical symptoms as above, are chronic hypertrophic turbinates, polyps, new growths and foreign bodies.

The accessory sinuses are namely the frontal, sphenoid, maxillary, anterior, posterior and anterior ethmoids. These are normal cavities in the skull, lined with mucous membrane and each emptying by their respect openings into the nasal chamber. Their function is believed to lighten the skull, warm the air, aid in phonation and maybe, the production of a bactericidal secretion. Due to their proximity to the nares and the predominance of many nasal deformities, these air spaces are frequently infected and many go on to a stage of chronicity and as such are frequently the etiology of unexplained cough, acute and chronic laryngitis, chronic bronchorrhea, asthmatic attacks and recurrent outbreaks of broncho-pneumonia simulating pulmonary tuberculosis. Darling in 1909 proved, by a series of post-mortem examinations that in a series of pneumonia cases the portal of entry was mostly an accessory nasal sinus. The writer would like to report two cases out of many cases illustrating these points. One a man with complaint of headaches, bad taste in the mouth and tickling sensation in the throat. Cocamization

he had been fishing and he partook of some of the fish he caught. He was suddenly seized with severe pain in the epigastrium. The pain returned two hours after eating and was very sharp in character. Bicarbonate of Soda and food gave him temporary relief. He was continuously nauseated and vomited once. He tried to treat himself for "ptomaine poisoning" because he thought his trouble came from the fish he ate. Finally the pain became so severe that he sought medical advice.

Physical examination revealed a well nourished and well developed individual. The tongue was coated. The pharynx was somewhat anemic. The chest organs were negative. There was marked tenderness in the epigastrium but no rigidity.

The systolic blood pressure was 136 and the diastolic 92. The gastric contents were HCL=55, total acidity 80, blood negative. The string test showed a blood strain  $18\frac{1}{2}$ —20 inches from the lips. The urine and the Wassermann were negative. Occult blood was present in the feces. The hemoglobin was 78% and the red blood cells, 3,900,000.

An X-ray of the stomach taken December 14, 1924, revealed a large niche 0.8 cm wide and 0.5 cm high on the lesser curvature (Fig IV).

The patient was treated at the Lexington Hospital with duodenal alimentation in a manner similar to Case No. 1. Within two days after the feedings were started the patient became symptom free. The progress of the course of the ulcer

of the treatment but it was ten weeks before all radiographic evidence of the ulcer disappeared. The patient has also been well ever since.

*Comment*—The pathological process of a penetrating gastric ulcer consists in the involvement of one or more coats of the stomach wall. The

Fig IV—L. S. December 14, 1924. Before treatment—niche on the lesser curvature of the stomach.

remaining coat or coats gave way under peristaltic pressure with the formation of the pouch-like bag. The margins of the ulcer are usually calloused and very often the neighboring organs are involved.

Pathologically we cannot differentiate a penetrating ulcer of short duration with a negative gastric history from an acute exacerbation of a chronic calloused ulcer. This was brought out by a case Kantor<sup>1</sup> reported. His patient was sick only one month. There was no previous gastric history. Still when the resected ulcer was submitted to the pathologist the latter reported that the microscopic sections presented the features of a chronic ulcer.

Radiographically we cannot differentiate the acute penetrating ulcer from the chronic calloused ulcer. Einhorn<sup>1,2</sup> has shown that we can outline the course and prognosis of a penetrating ulcer of long standing by means of the roentgen ray. He also pointed out how long it took for the niche to disappear. In the two cases I have reported it took seven weeks and ten weeks respectively before all radiographic evidence of the ulcer cleared up. This is about the average length of time it takes for a niche of a chronic calloused ulcer to disappear.

It has been the experience of all of us to witness an acute perforation or a severe gastric hemorrhage in a patient who never had any trouble with his digestive tract. Why cannot a penetrating ulcer occur without a previous history?

It is conceded by all that the history of an ulcer

Fig III—Mrs. W. June 12, 1924. After treatment—niche disappeared.

was checked up periodically from the time the treatment was started. The niche was present in all the roentgen examinations that were made up to Fig V, which was taken ten weeks after the treatment was started. Here again the patient was symptom free a few days after the beginning

the other fourteen days Both of these patients were emphatic in their assertions that they never had any gastric disturbances prior to the onset of the present affection

*Case No 1*—Mrs E W, age 30, white, married, was first seen by me on April 11, 1924 The patient gave the following history

Family and previous history negative Appetite was always good and the bowels were regular The patient never had the slightest gastric disorder until ten days previous At that time, she began to complain of a sudden sharp pain in the epigastrium fifteen minutes after eating The pain did not radiate Sodium Bicarbonate relieved the pain the first few days and then the pain became so severe that hypodermic injections of morphine became necessary There was no vomiting

Physical examination showed that the patient was well nourished The head and chest were negative The abdomen was soft There was marked tenderness in the epigastrium No masses were palpable.

The systolic pressure was 120 and the diastolic 76 The gastric analysis showed free HCl=60, total acidity = 75, blood-trace The string test was negative for an ulcer The feces were negative for blood The hemoglobin was 75% The red blood cells were 3,550,000 The Wassermann was negative The urine had a specific gravity of 1015, no albumin, sugar or indican

A roentgen examination of the stomach was made on April 11, 1924 It showed a niche on

series showed that the same niche was present on the lesser curvature (Fig 2)

The patient was then admitted to the Lexington Hospital I treated her with duodenal alimentation An Einhorn duodenal tube was inserted April 22, 1924, and the feedings were

Fig II—Mrs W, April 15, 1924 Before treatment—after atropine sulphate for three days—niche still present

started the next day The usual formula of one egg, eight ounces of milk and one tablespoonful of lactose given every two hours was used for the feedings A powder was given three times daily composed of Lupulin gr 1/2, Calc Magnes, gr IV—Bism, Subcarbonate gr xxx

Within twenty-four hours after the duodenal alimentation was started the patient was free from pain The duodenal feedings were kept up for fifteen days The tube was then removed and the patient allowed a gradual return to a normal diet, which took about two weeks from the time the tube was removed

Although the history of the ulcer was a very short one, nevertheless I followed the same plan of treatment that has been used in peptic ulcers of long standing

The progress of the lesion was checked up radiographically at various times The last X-ray was taken June 12th 1924 (Fig 3) Although the patient became symptom free a short time after the treatment was started the niche did not disappear before seven weeks

The patient has been perfectly well since the treatment

*Case No 2*—Mr L S, age 35, white, married, consulted me on December 14th, 1924 His history was as follows

Family and past history negative The man had always enjoyed good health His appetite was good and his bowels were regular He always ate and slept well and never had the slightest gastric discomfort Fourteen days previous

Fig I—Mrs W, April 12, 1924 Before treatment Niche on lesser curvature of stomach

the lesser curvature that was 0.3 cm high and 0.3 cm wide (Fig 1) In order to preclude the possibility, that functional spasm and not an organic lesion was the cause of this niche, I gave the patient atropine sulphate gr 1/120 twice daily for three days and again took an X-ray This

Her general health had always been good, except for an attack of tonsilitis two years ago. She had palpitation of the heart, subjective heat, and perspired easily. Her appetite was normal. She menstruated very irregularly, frequently skipping several months, but flowing profusely for seven days when it did occur. She urinated four to five times during the day and two to three times during the night. She said she was irritable, tired easily, and had poor emotional control. She had lost a little weight.

*Physical Examination*—The patient was slightly obese, weighing 162 pounds, and was quite "fidgety" during her examination. Pulse was 132, blood pressure 140/90, basal metabolism +50, (five days later +29). There was slight tremor of the hands, but no eye symptoms. The heart was regular, not enlarged, and no murmurs were heard. The urine contained no albumen or sugar.

There was a moderate enlargement of the thyroid gland, especially of the right lobe and isthmus. The consistency was soft and uniform and there was no deviation of the trachea.

No evidence of any tetanic irritability of the muscles was noted, although this was not definitely looked for.

A diagnosis of primary hyperthyroidism was made.

She was advised to stop nursing and was kept under observation. After two months, her pulse taken twice daily by herself ranged from 116 to 140. She began to feel "choky" and her thyroid had definitely become larger and firmer. She was started on Lugol's solution, grs V, t.i.d., with the idea of preparing her for operation, but after a few days had another attack of tonsilitis with temperature 103 and pulse 160.

On January 1, 1926, she was again started on Lugol's solution, entered the Deaconess Hospital on January 4th, and the following day a bilateral subtotal thyroidectomy was done. At this time her pulse was 96-120.

*Operation*—January 5th 1926. Two hours before operation, scopolamin, gr 1/300 morphine, gr 1/4, atropine, gr 1/150 were given. Gas-oxygen anesthesia was given by Dr Oscar Stover. The greater part of both lobes and most of the isthmus were removed, taking the usual precaution of leaving the postero-internal portion of each lobe untouched. The operation went smoothly, lasting one hour. The pulse went up to 155. The blood pressure at first went up, then came down slightly.

*Post-Operative Course*—There was no severe reaction, the highest temperature during the first 48 hours being 101, pulse 112.

On the morning after operation on being asked how she felt, she said "I am feeling fine but look at my hands, I cannot open them." Both hands were held in the typical "accou-

cheurs" position and the skin was glossy. Constriction of the forearms increased this contraction and made it painful (Trousseau's Sign) and Chvostek's Sign (contraction of muscles of face on tapping facial nerve) was marked on both sides.

The specimen removed at operation was now more carefully examined, serial section being made by Dr Theodore Mueller, pathologist of the hospital, but no trace of any parathyroid bodies could be found.

The patient was given calcium lactate, gr X q 4 h, and that afternoon the hands were perfectly relaxed.

January 7—Both hands flexed again, face swollen some cramps in legs. Calcium lactate increased to gr XX q 4 h.

January 8—Condition unchanged, but that evening both hands were free and there was no sign of tetany.

January 9—Early in the morning patient had a severe spell of dyspnoea. Both hands were tightly flexed, muscles of neck, throat and chest were in a state of tetanic contraction, making breathing almost impossible, with constant painful twitching in various parts of the body. The condition of the patient was most pathetic and at times it seemed as though the end were near. After lasting about one hour, it was finally controlled by large doses of morphine.

During the eight following days that she remained in the hospital, she had four more similar attacks, though not quite as severe as the first one. In the intervals, her hands and feet were flexed most of the time, her face was swollen and Chvostek's Sign was always present. She was given increasing doses of calcium lactate, also calcium chloride, parathyroid extract and thyroid extract.

She left the hospital January 17 and improved slowly for a few days.

On January 22nd, she had another severe attack, followed by other attacks on January 29, February 9, February 10, February 13, and February 14. In addition to the other drugs mentioned, bromides and chloral were given. On February 20, Collip's Parathyroid Serum (Parathormone, Lilly) was first given, starting with 1 cc (20 units) hypodermatically daily for a few days and then 1/2 c.c. daily. From that time on she had no more attacks. All other drugs except calcium lactate were discontinued.

Beginning March 1, 1/2 c.c. of the serum was given at increasing intervals until on July 23 the interval was 12 days.

Until June 1 her hands still tightened up, especially when she became nervous, but since then they have been normal and on July 23 even her Chvostek's Sign was gone for the first time.

patient gives us an approximate idea of the duration of the affection. This gives rise to the following question: Must an ulcer exist an appreciable length of time, even though it be dormant, before it can give rise to symptoms or can an ulcer develop in a perfectly healthy individual who never had the slightest trace of gastric lesion?

Ashoff<sup>5</sup> states that a penetrating gastric ulcer can arise in a few days in the life cycle of a chronic ulcer. But this does not explain the presence of an acute ulcer in a patient who, to the best of our knowledge, never had a sign or symptom indicative of the existence of any such affection. Plaut<sup>6</sup> explains the presence of these ulcers as follows:

Plaut maintains that ulcer patients should be divided into two groups:

1. Ulcusträger or ulcer carriers

2. Ulcuskranke—those that have clinical manifestations of an ulcer

In the former are grouped those patients that go along for many years with an ulcer that lies dormant. The individual is symptom free until some exciting factor arises. In the second group Plaut places those cases where the individuals have active symptoms as a result of the ulcer.

Plaut's theory is very interesting. It offers an explanation as to why a penetrating ulcer with a history of a short duration cannot be differentiated pathologically and clinically from a chronic ulcer. This is of the utmost diagnostic as well as prognostic importance. It follows, therefore, that these cases must be treated along same lines.

We must not minimize the patient's complaint because he never had any gastric disturbances before. The history should not mislead us. I am sure if we are on the alert we will find cases of this type of even shorter duration than those here.

#### SUMMARY

1. Penetrating gastric ulcers with a history of short duration occur without a previous gastric history.

2. These cases should be treated the same as chronic ulcers.

Fig. V—L. S., February 28, 1925. After treatment—niche disappeared.

## A CASE OF POST-OPERATIVE PARATHYROID TETANY CONTROLLED BY THE USE OF COLLIP'S PARATHYROID HORMONE

By ALFRED H. NOEHREN, M.D., F.A.C.S., BUFFALO, N. Y.

THE occurrence of tetany following thyroidectomy is such a tragic condition and the treatment of the severe cases has been so unsatisfactory in the past that the following case in which the use of Collip's serum seemed to cure an otherwise hopeless case should be of interest. A few similar cases in which this serum has been successful have already been reported and this report is added to strengthen the evi-

dence in favor of the efficacy of this rather recent therapeutic agent.

#### REPORT OF A CASE

E. W., a nurse by occupation, was first seen September 5, 1925. Her chief complaint was shortness of breath, coming on six months previously and getting worse. At about the same time she noticed that her neck was getting larger.

ease, quoting a writer to the effect that since God has put medicinal herbs on the face of the earth, no sensible man would neglect them, and adding that "like unto a murderer is the physician who refuses to tender his assistance in time of necessity, or who practices without due study of the ailment he is treating"

In his *System of Therapeutics*, based upon some thirty works of Galen, he stated that "in minor ailments Nature cures the body without the need of medicinal remedies if the patient only follows certain dietetic regulations" "When," he continued, "the services of a physician are required, he should see to it that he aids Nature in her beneficial course. Most doctors err in their treatment. In endeavoring to assist Nature they weaken the body with their prescriptions"

Similar valuable and practical advice can be found in other of his works, the complete list of which is long, and includes

An imitation of and a commentary upon the aphorisms of Hippocrates, a treatise on the causes of disease, enumerating the etiological factors in various illnesses and logically correlating the cause and effect of disturbances of health, an Arabian pharmacopeia called *An Explanation of Drugs*, a Consultation on Snuffing in the Nose and Throat, and another Consultation on Accidents, a treatise on asthma, giving the symptoms and treatment, with various case reports from Arabian physicians, essays on sexual intercourse, medical consultation, gout, physiology, personal hygiene, stomach, and brains, and his two best known treatises, namely on Physical Hygiene and on Poisons, which have recently been translated into English<sup>1</sup>

The medical works of Maimonides, despite their intrinsic worth, have received comparatively very little consideration in English. Originally conceived in Arabic, his many manuscripts have been translated into the Hebrew language, and to a lesser extent into the German and French. Steinschneider, the learned medical historian, has devoted a great share of his researches to rendering the texts of Maimonides into German.<sup>2</sup> Pagel<sup>3</sup> and Ratner<sup>4</sup> have similarly treated of Maimonides as a contributor to medical literature. Other studies from this angle are to be found by Max Kahn<sup>5</sup>, Mendelsohn<sup>6</sup>, Yellin and Abrahams<sup>7</sup>, and in the Jewish Encyclopedia

Although a careful study of these writings show a lesser degree of actual originality than scientific learning, they do demonstrate the fact that he was familiar to a marked extent with the older and reputable authorities. And similarly, although they also indicate his reliance on precedence, they show that he tested his remedies by actual experience and that he recognized how deeply physical conditions are effected by psychic causes. A consideration of his treatise on hemorrhoids will substantiate these assertions

In the course of a search for original Arabic texts of Maimonides, H Kroner, a German scholar of medical history, chanced upon a six octavo-paged manuscript of twenty-five lines to the page, which proved to be the oft-mentioned but little known treatise on hemorrhoids. With meticulous care he then presented a critical and comprehensive interpretation of this work, giving in addition copious notes and a Hebrew and German translation. The following material is based on this German translation, in Janus, volume xvi, for 1911<sup>8</sup>

In the introduction to his study, which he calls "Hemorrhoids in the Medicine of the 12th and 13th Centuries," Kroner gives a review of the current knowledge of that ailment, leading up to an historical and scientific valuation of the contribution of Maimonides. An analysis of this treatise reveals at the onset some characteristics typical of many of the medical writings of the prince of physicians

One recurrent feature is a short prayer to God, at the beginning and close of the essay, for he always kept close to the spiritual side of life. And another is his customary dedication to some distinguished person for whom the work was expressly prepared, as exemplified in the treatise on Poisons, on Physical Hygiene, Asthma, and Coitus. The inspiration for the work under consideration is revealed in Maimonides' introduction

"A youth of prominent and renowned descent was afflicted with anal hemorrhoids which irritated him for a long time. He attempted to heal them in the usual manner with the result that the pain subsided, the swellings decreased, and the normal functions were resumed. But since they recurred many times, he desired to have them removed surgically, thus completely extirpating the cause of his sufferings to the extent that they would never return again"

Maimonides then informed his patient that all types of hemorrhoids were not amenable to operation, and in addition, even then they would frequently come back owing to the fact that the original cause still remained. He accordingly offered for his benefit a curative regime which could constantly be adhered to, and which was especially easy "for a coddled youth to follow"

The treatise, which was prepared by way of a prescription, is divided into seven chapters which take up pertinent phases in the manner of easing the burden of the *golden reins*. Not intended, the author explains, as a complete guide to health, it is nevertheless a valuable code for victims of this disease to follow

In recognition of the fact that most illnesses hinge upon poor digestion, a consideration is first given to the regulation of the diet, which calls for four precautions, namely, in regard to the quantity and quality of the food, the sequence of foods,

She went back to nursing on June 1 and has been perfectly able to do her work ever since.

Her wound healed up perfectly in record time and her pulse soon became normal, excepting during her attacks.

Unfortunately we were unable to get blood calcium determinations during her illness and the parathyroid serum had to be given cautiously to prevent a condition of hyper-calcaemia. On August 23, her blood calcium was 7.2 mgm per 100 c c.

*Comment*—The parathyroid glands were discovered by Sandstroem in 1880. The relation of the parathyroids to calcium metabolism was discovered by MacCallum and Voegtlin in 1909. Since then calcium has been the best remedy available in the treatment of parathyroid tetany.

Transplantation of parathyroids, except autotransplantation, has been without results. Recently Lahey<sup>1</sup> advised searching every thyroid removed at operation for parathyroids and, if found, immediately transplanting them into the sterno-mastoid muscle. The use of parathyroid extracts has also been unsuccessful.

With the above forms of treatment, calcium, parathyroid extract, and gland transplantation, the death rate has been very high. Thus Billroth reported 50%, and Grossman 25% mortality.<sup>2</sup>

In 1925 Collip<sup>3</sup> extracted a hormone from the parathyroids of oxen by the use of which the blood calcium level in parathyroidectomized animals could be maintained and thus tetania parathyreopriva prevented or controlled. Its clinical use was advised in cases of tetany and reports thus far submitted, as the one above, seem to confirm clinically the experimental findings.<sup>4</sup> According to this evidence Collip's serum seems to be a specific in the treatment of tetany equal in value to the use of insulin in diabetes.

Fortunately tetany is a very rare occurrence following thyroid operations, at least among American surgeons. Thus Lahey reports only

two cases in 3,100 thyroid operations. This is probably due to the fact that subtotal thyroidectomy is the operation of choice in this country, leaving behind the postero-internal portion of each lobe, which is in intimate contact with normally situated parathyroids. The occurrence of tetany is much more frequent where extracapsular thyroidectomy is done. Thus v Eiselsberg reported 23%, and Grossman 30% of tetany after the bilateral operation and Reverdin 25%, and v Eiselsberg 5% after unilateral operation.

Nevertheless, even in subtotal thyroidectomy and in spite of all these precautions, tetany will occasionally occur and for these reasons. In some individuals there is less than the normal amount of parathyroid tissue and any operative interference may cut off enough of its blood supply to cause tetany. Occasionally the parathyroids lie in abnormal positions, sometimes even being embedded in the thyroid tissue. In the case reported, no trace of parathyroids could be found in the specimen removed. We must assume, then, that the tetany was due to interference with the blood supply in a patient who perhaps, was already deficient in parathyroid tissue. A routine preoperative blood calcium determination would make it possible to recognize such a deficiency before operation. In that case the patient could be prepared for operation by treatment with the serum until the blood calcium is normal and perhaps less thyroid tissue be removed than would otherwise seem indicated.

## MAIMONIDES' TREATISE ON HEMORRHOIDS\*

By LOUIS J BRAGMAN, M D, SYRACUSE, N Y

Moses Maimonides, the peer of twelfth century physicians, was born in Cordova, Spain, in 1135 and died in 1204, leaving behind a written record of philosophy, religion, and medicine that serves to make him the greatest of great men of his time. At an early age he studied under distinguished Arabic teachers, becoming proficient in mathematics, philology, natural sciences, medicine, logic, and metaphysics. In 1165 he took up the practice of medicine in Cairo, Egypt. It was not long before he achieved unusual success by virtue of

his remarkable ability as a practitioner, and in 1174 he was made private physician to the Vizier Alfadhel, declining subsequently a similar offer from Richard the Lion-Hearted, King of England.

His medical works reveal an extensive and varied range of experience. In the *Guide to the Perplexed*, a classical code of ethics, he devoted sections to dietetics, stating that the variety of food taken should not depend upon taste or caprice, but upon certain physiological principles aiming to enhance health and the usefulness of the body. In his Commentaries on the Bible he gave various medical opinions on the treatment of dis-

\* (Read before the Syracuse Academy of Medicine March 1 1927)

root of fenugreek. The technic is simple. Build a coal fire in a hole in the ground. Place over this a bowl that has a hole in its bottom the size of a nut, and make an embankment around the bowl so that the smoke will come out only through the small opening. Throw any of the above-mentioned ingredients on the fire, and when the smoke arises, sit on the bowl. This should be done three times an hour, and once a week as well as a precaution.

This is the substance of Maimonides' treatise on hemorrhoids. The regulation of diet, the listing of foods indicated and contra-indicated, the local and systemic remedies, the radical and conservative measures—all these bespeak a decidedly modern trend. And the entire treatise verifies Maimonides' own contention that the aim of the doctor is to prevent illness more than to cure it.

H Graetz, who has written extensively of Maimonides in his *History of the Jews* asserted

that he prescribed no recipe for whose efficacy he could not cite the judgment of the leading authorities. That he was not one to rely solely upon the opinions of others, his very large practice indicated. There is no doubt but that he tried and approved repeatedly the measures he recommended for the prevention and cure of hemorrhoids.

## SOME OF THE EARLY MANIFESTATIONS OF CORONARY DISEASE\*

By DAVID GREENBERG, M D, NEW YORK, N Y

**I**NTRODUCTION. Atherosclerosis and occlusion of the coronary arteries has received so much attention in the literature lately that it is no easy task to add anything that is new to the subject. My excuse for adding to an already extensive literature is the frequency with which the early manifestations of this disease are overlooked. Typical cases of coronary disease, especially occlusion, are so dramatic in their onset and so often tragic in their progress that the less outspoken signs may not be heeded, or they may be misinterpreted. Early in this disease the so-called clinical picture of coronary disease is often conspicuous by its absence. Naturally therefore the diagnosis is not made unless one keeps in mind the fact that this disease, especially in its early period of development, often expresses itself in a bizarre manner. For it is not uncommon to have patients who have disturbances of their coronary circulation, operated upon for gall-stones, or have their chests strapped for pleurisy. One of my patients underwent prolonged treatment for peptic ulcer when he was actually suffering from coronary disease.

That there is no real parallelism between the clinical expression of this disease, and the pathologic picture as found post mortem is known to all students of this malady. To be sure one often finds most advanced disease of the coronaries which gave not the slightest inkling of its existence to the clinician, death having occurred from an unrelated disease. The reverse is true, where the suffering of the patient is pronounced and

relatively little pathology is found, is also true, but not with equal force. It is clear therefore that even with fairly advanced disease, and the best condition for observation a clinical diagnosis of coronary disease is difficult and at times well nigh impossible. It is manifest that emphasizing the early features of this disease will serve to focus attention on the cardiac circulation at the time when medical management and supervision will do most good. When the heart is riddled with areas of fibrosis, aneurysm and pericarditis due to inadequate circulation in the coronary of long standing it is obvious that little may be expected by way of staying the disastrous end results. Once the stage of multiple infarcts in the heart muscle is reached the patient is beyond relief.

Before attempting to stress the early picture of coronary disease a brief definition of the term coronary disease will be given. Mention will also be made of some of the salient features of this disease as ordinarily encountered. No attempt will be made to cover this vast subject in any comprehensive way. On the pathology alone of this disease a number of good size monographs have been written, and the clinical side has a very voluminous and extensive literature.

*Definition.* Coronary disease may be defined as disturbances of the circulation of the heart with resulting ischemia of the heart muscles, temporary or permanent. It is usually caused by atherosclerosis and thrombosis of the coronary arteries or their branches. Pathologically there may be evidence of infarction either recent or old, in addition to various degrees of atherosclerosis

\* Read before the Bronx County Medical Society January 19, 1927.

and the time for eating. Even good food is harmful if too much is taken. The appetite should never be fully satisfied. Poor food, even though perfectly digested, gives rise to bad blood. An excess of peppery foods, cucumbers, onions, garlic, cabbage, vinegar, and lemons should be avoided. Bread, meat, eggs, and honey are the safest kinds of food. Malodorous and decomposed foods are, in the words of Galen, as harmful as deadly poisons. Take lighter foods first, thus stewed cabbage before eggs, eggs before fowl, fowl before mutton, and lemon before sumac or pomegranate. Drink cold water only about an hour after leaving the table. Eat only when hungry, take exercise before meals and avoid all kinds of excitement, mental or physical directly after meals.

These general rules of diet, Maimonides emphasizes, are of prime value, if adhered to, in lessening the possibility of hemorrhoids.

In logical order, he next discusses the foods which should be especially avoided. Inasmuch, he contends, as hemorrhoids for the greater part have their origin in *black bile*, those articles of nutrition should be shunned which tend to make the blood thick and *muddy*. For if the blood acquires this character, by force of gravity the sediment in it sinks to the lower parts of the body, and especially to the vessels around the anus, which eventually become permanently congested and enlarged.

The hemorrhoids that thus arise are of two types, those that bleed, and those that do not. The former state is more advisable, for thus a safety measure is afforded against the development of insanity, melancholy, and epilepsy. The second type should be opened to forestall these nervous ailments. But dietary precautions are better still. Foods which tend to form black bile by heating and thickening the blood are beans, lentils, cabbage, melons, sumac, beef, goat's meat salted meats, dates, old cheese, unleavened bread waterfowl, brains of animals, and vinegar.

On the other hand, certain foods are beneficial in alleviating hemorrhoids, such as the broth and meat of fat fowl, yearling sheep, fat of roast loin, cakes made with egg-yolk, peas cooked in oil of almonds, Indian nuts, dried figs, and anise seeds.

In chapter four certain internal remedies are prescribed, to be taken in large quantities. A good preparation is myrobalan, an Indian nut, mixed with sugar and anise seeds. Another mixture consists of washed and ground iron slag one and a half drams of which are mixed with wine. Mace makes a good drink for hemorrhoids. A special electuary which Maimonides prepared for his patient contained myrobalan, kebulum, belliricus, emblicus anise bdellium, aristolochin, mastic, mace, and lepidium, ground together in specified weights mixed with oil of almonds and

taken in broth of steer's tongue continually, except during extremes of weather. Arrazi, we are told, prepared a dose of one part each of myrobalan, kebulum, and emblicus, one half part iron slag, two parts bdellium, mixed in garlic water, and rolled into pills.

Of the local remedies, oil of Indian nuts, castor oil, spikenard oil, and jasmine oil are effective. Bdellium and extract of lead are particularly penetrating. An effective clyster is made of two ounces of garlic water, one ounce of celery water, oil of nuts, and oil of turpentine or castor oil, each one ounce, radishes, one ounce, mixed together, boiled, and used every two or three months. A very good remedy is prepared by taking two ounces of one of the above mentioned oils, one ounce of pomade of dates, and one ounce of blue bdellium, these are heated over a gentle flame and then pounded in a lead mortar, with a quarter of a dram of saffron, in the sun for an entire day (the one who does the pounding sitting in the shade). The pain is readily eased if this concoction is smeared on the "piles." But one should not nullify these methods by sitting unwisely on cold marble, or by douching the anus with cold water, except in the summer.

Chapter six deals with methods of combating the more severe types of hemorrhoids. If the situation is very urgent, and the patient can stand it, bleeding is resorted to, but if the patient is too weak, cupping-glasses are placed between the hips, and in addition the internal and external remedies are used. Another valuable procedure is to sit in warm water in which leaves of althea or melilotus or linseed or camomile or cottonseed have been steeped. A good local application consists of starch mixed with sesame oil, fat of duck or hen, and a little saffron. Another formula contains one ounce of oil of apricot seed, in which are dissolved two drams of balsam, two drams of bdellium oil of roses, egg yolk, fat of duck or hen, and saffron. Ibn Wafid boils one ounce of oil of roses, well perfumed, with three ounces of white wax. Arrazi kneads two drams of zinc oxide and one dram of Indian lycium into an ointment made of Ibn Wafid's mixture. Avicenna had good results with a preparation made of two drams each of serafinum, and bdellium, one dram of balsam, one half dram of opium, one and a half ounces of oil of apricot seed, dissolved together over the fire, to which one-half of a dram of powdered castoreum is added. Finally, Maimonides states that the fat of crocodiles mixed with oil of roses is said to be especially alleviative.

The last chapter deals with a method of treating hemorrhoids by means of medicated vapors, a not unusual procedure at that time. Some of the substances employed are sandarac, garlic seeds, serpents' skins, colocynth, cottonseed, seeds of wild rue cicuta seeds, long aristolochin, and the

accustomed tasks and coming on after a heavy meal or periods of prolonged activity is another early signal that the coronaries are no longer adequate. Ordinarily when the coronaries are soft, elastic, and resilient, increased demands on the heart results in an increase in the circulation in the coronaries by reason of the stripping action of heart muscle (Wiggers). When the walls of the arteries become calcified and rigid this stripping action and consequent increase in blood flow, no longer takes place. The viscerocutaneous reflexes of pain accompanied by nausea, and weakness, and a sense of air hunger then becomes manifest.

Another mode of onset of this disease is a tendency to sinking spells, or spells of extreme weakness associated with a peculiar empty or vacant or fluttering sensation in the precordium. It is surprising to see how often the story of repeated attacks of weak feeling in the precordial area especially when the subject is a female, is dismissed as being irrelevant and unimportant. While it is undoubtedly true that many women are subject to fainting spells and weak spells who have no demonstrable organic disease one should at the same time bear in mind that such attacks may be the first indication of profound disturbance in the coronaries. Other evidences of heart failure are most often entirely lacking. Unlike heart failure due to chronic valvular disease and so called cardio renal disease with or without hypertension symptoms of congestive decompensation are usually not present here. If one looks for confirmatory evidence of failing circulation in other organs, such as enlargement of the liver, pulmonary stasis ascites or oedema of the lower extremities one will be disappointed. Indeed, even orthopnoea is usually absent and at times even in the presence of occlusion of a fair size vessel. Nor is dyspnoea an outstanding feature of this disease. However, one is not deprived of helpful suggestions when a general survey of the patient is made. Departure from the normal color, such as pallor of the lips, face and hands, and mottling of the forehead and lips are extremely valuable aids in the early diagnosis. Dusky cyanosis and ashen gray hue to face and hands are later manifestations. Evidence of arterio sclerosis elsewhere in the body especially in the fundi, radials, dorsalis pedis, posterior tibials and temporals are helpful in demonstrating the tendency of a given patient towards atheromata. In some cases intermittent claudication of the lower extremities may exist at the same time as intermittent claudication of the coronaries. Confusion should be avoided between the extreme weakness in the lower extremities consequent to coronary disease and the pain in the lower extremities due to ischemia because of local atherosclerosis.

In addition to the pain and pallor, immobility

on the part of the patient is rather characteristic of this disease. During all stages of this disease when a paroxysm occurs the patient holds himself still and refuses to move or be moved. This sensation on the part of the patient probably arises from the subconscious and is an instinctive expression of self preservation. One has but to think of the gyrations, gymnastics, and distortions of the patient who is suffering from either renal colic or gall bladder colic to profit by the comparison. In this disease even in the face of very severe pain the patient holds himself quiet and wishes to be left alone. He assumes a rigid almost breath holding attitude with the possible exception of putting his hand where the pain is most severe. One can't emphasize too forcibly that the triad of pain, pallor, and immobility even when relatively slight are sufficiently to make a diagnosis and that in the face of normal graphic findings. In fact graphic methods are not very helpful in this disease.

When in the presence of the above symptoms one finds an appreciable fall in the blood pressure, the diagnosis may be said to be clinched. This is especially true when the color manifestations are marked. It may be profitable perhaps to stress again the mottling of the lips and the forehead as a very valuable diagnostic sign. An ashen gray appearance of the patient is very characteristic, but that occurs late in the disease. Mottling of the lips, on the other hand, may be and often is an extremely early phenomenon. Mention must also be made of another valuable sign, and that is muffling of the heart sounds. And while this is usually a late occurrence, at times it may make its appearance early. The same holds true for a pericardial friction rub. It is usually due to occlusion of a fair size vessel with resulting infarction of the heart, but once in a while it occurs rather early in the disease. Tachycardia, leukocytosis and a rise in temperature are late manifestations of the disease, and are only mentioned here to complete the picture. If one waits for them to appear, one may not have the privilege of making an early diagnosis. Head zones of hyperesthesia in the skin have not been present often enough to be of material help. When they do occur, however, they may be regarded as additional evidence.

*Case Reports*—It has been my good fortune to observe some of these suffering from coronary disease from the very beginning of their ailment. I will relate some of their histories in brief, so that we may gain an insight into the difficulties of early recognition of this disease.

Case 1—W. S., age 50, occupation, insurance agent, came to see me in October of 1921 complaining of slight pain in the precordium and just below the right clavicle. This pain was especially annoying when walking and became

and thrombosis of the coronaries themselves. At times thinning of the ventricle occurs. This may go on to aneurismal dilation and even rupture of the heart. Areas of pericarditis over the infarcted portions of the heart is a common occurrence. Clinically the symptoms vary a great deal. Sudden almost instantaneous death occurs when a large vessel is occluded or when rupture of the heart takes place. At other times symptoms are so mild in nature to warrant diagnosis of dyspepsia, myositis, or intercostal neuralgia.

**Causation** Fascinating as it is, to speculate about the cause for things in general, the cause of this disease is no better known than the cause for atherosclerosis elsewhere in the body. Of the usually mentioned causes faulty diet, focal infection, alimentary toxic products, metabolic waste products may be dismissed as platitudes. It is possible that hereditary influences play a not unimportant role especially under the strain and stress of modern life. Syphilis, diabetes, among the chronic diseases cannot be entirely dismissed as contributing factors. Experiments with bacterial toxins have yielded no positive results. One must maintain an open mind as to the cause of this disease until better proof is adduced.

The age of the patient when coronary disease may occur is variously given by different observers. Comparatively young individuals may be afflicted. It is not uncommon to find some evidence of roughening of intima and even plaque formation as early as the third or fourth year of life if a careful search is made. In my experience a man 33 years of age was the youngest individual in whom a fairly severe attack of coronary disease occurred. The ages between forty and sixty yield most cases. The male sex appears to be more commonly afflicted.

**Symptomatology** In a general way it may be stated that subjective manifestations of this disease predominate and they appear earlier than objective findings. Atherosclerosis is rather slow in its development and the earliest manifestation of its existence is pain. This pain may be slight almost trivial at the beginning and considered insignificant by the patient. *Pain by far is the most important single symptom of this disease.* The location, severity, character, and radiation of the pain varies considerably. Patients differ a good deal in their description of the pain. During the early stages of the disease they usually complain of (1) a dull ache, (2) a gnawing pain, (3) a sharp lancinating pain, short in duration, and coming on after exertion or meals. As the disease progresses they describe their pains as being pressing or choking in nature. In the very severe cases, a vise-like agonizing, through and through pain so severe that they are afraid to move is experienced, this is usually accompanied by a sense of impending dissolution. This latter is the angina pectoris of the older writers.

The location of the pain is most frequent in the precordial area. The dull ache, the gnawing pain, the choking and pressing pain, the boring pain, and the through and through pain is often limited to the precordium only. In the vast majority of cases however, the pain radiates into one of the following areas: (1) into the left shoulder, left arm, left wrist and left axilla, (2) through and through to the back and left scapular region, (3) into the epigastric region, (4) into the base of the neck and suprasternal notch (the choking sensation is very frequent in the same area), (5) into the right shoulder and the right arm, (6) into the right upper quadrant of the abdomen (liver and gall bladder region), (7) into the back of the neck and base of skull. More rarely the pain radiates into the flanks, more particularly the left. Still more infrequently the pain may radiate into the thighs and legs. There may be local sweating associated with these attacks of pain. This latter phenomenon is said to be due to disturbances in the motor arc of the cervical sympathetic through which visceral cardiac pains are alleged to be carried to the brain and referred back into the various skin segments.

As to what significance to attach to the symptom of pain, the personality of the patient must be considered. Neurotic individuals naturally regard pain much more significantly than does the ordinary person. Nevertheless, a dull ache in the precordium which is aggravated by exertion, excitement, or a full meal, is an extremely valuable sign, occurring as it does, early in many cases. Such pain is almost invariably aggravated by walking, especially rapid walking, and is usually accompanied by extreme weakness in the legs. When the pain is associated with nausea it is almost pathognomonic of coronary disease. Next infrequency to the dull ache or gnawing pain is the lancinating pain which comes and goes but is aggravated by exertion or a full meal. The story usually is that in attempting to walk any distance the patient has to stop every block or so because of the discomfort in his precordium. Careful questioning often yields the information that slight pain preceded by many years a typical attack of coronary occlusion.

Even in this early stage of the disease, some patients will sense the gravity of their ailment. When they consult a physician they are sometimes told that they are nervous and to try and forget all about it. Similarly pressure pain, and pain with a sensation of choking are also disregarded by some medical attendants, who erroneously diagnose these cases as being due to globus hystericus. One ought to be mighty sure of his ground before thus designating cardiac pains.

A peculiar sensation of a combination of nausea and discomfort in the epigastric area or a fluttering sensation in the substernal region especially when associated with inability to perform

walk for more than a half block without experiencing sharp precordium pain

*Treatment*—There is no therapeutic panacea for this disease. It is not known how to prevent the change in the wall of the arteries of the heart. If an early diagnosis is made, one may be able to give symptomatic relief and undoubtedly prolong life. It is not my intention to go into any detail as to symptomatic treatment. This must be obvious to any well trained physician. Nevertheless, one may be permitted to stress certain general principles.

*Relaxation*—The patient must be taught the art of relaxation. He must be taught to assume a philosophic attitude towards life and he must be taught to understand that the savage life of this civilization, more particularly city life, will only get him into an impasse. The futility of the hustle and hurry and the harmfulness of relentless ambition in whatever field must be pointed out to him. He must be helped to read to rest and to cultivate some intellectual hobby. Early in the disease, bed rest is quite essential. Later, when he improves the curtailment of the hours of work and the advisability of frequent vacations must be impressed upon him. If the patient is obese it is a good plan to make him reduce in weight. Meals should be small and frequent. Of the drugs, it is but necessary to mention a few that may be used. The group of vaso-dilators more especially nitro-glycerine and erythrol tetranitrate, are valuable. Amyl nitrate may be used during an attack of severe

pain. Alcohol in the form of wine in moderation has been found most useful by many who have had considerable experience with this disease. It probably acts on the brain, permitting the patient to become more or less relaxed and perhaps dulling the driving power which most of us possess to an abnormal degree. The bromides are equally valuable in releasing the patient from a too active mentality. Digitalis is very often used in small doses. Its advisability in this class of cases is a moot question. In my experience small doses have been found beneficial to most patients. Morphine and its derivatives have to be employed in many of the cases and should not be withheld. Diuretin and other members of the caffeine group so highly recommended by some, have not been found of particular value in the majority of cases. Once in a while the response to diuretin is remarkably good and in that event it may be continued over a long period of time. Enphylin is another drug that is often useful.

#### CONCLUSION

- 1 Coronary disease is not a rare disease and may occur comparatively early in life.
- 2 Pain, especially when associated with pallor and immobility, enables us at times to recognize this disease relatively early.
- 3 Mental and physical relaxation and curtailment of all forms of activity are the objectives to be attained in the management of this disease.

## THE KAHN PRECIPITATION TEST FOR SYPHILIS IN COMPARISON WITH THE WASSERMANN RESULTS

By RUDOLPH J SHAFER, M.D.,

Director, Steuben County Laboratories Corning N Y Hornell, N Y Bath N Y

THROUGHOUT the medical world today the Kahn precipitation test for syphilis is attracting much attention. Numerous articles have appeared in the medical literature during the past few years on the Kahn test. There has been both praise and criticism although the recent reports are almost invariably in favor of this test as compared with the Wassermann. Laboratories all over the country are now doing the test, either alone or in conjunction with the Wassermann. On December 31st, 1925 the United States Navy adopted the Kahn test as the official method for the serum diagnosis of syphilis. The Laboratories of the State Department of Health in Michigan have replaced the Wassermann by the Kahn precipitation test.

Various workers have attempted to perfect a precipitation test that would be practical of these the Meimicke and Sachs-Georgi are prob-

ably the most well known. Not one of the tests however, has received universal application as they have all required more or less incubation to produce precipitation.

Kahn has based his test upon a sound principle, every step an observed fact. The success of the test depends not on incubation but upon concentration of the ingredients, namely the patient's serum, antigen, and normal salt solution.

In this test the stronger sera show complete precipitation in about 15 seconds and the weaker sera in approximately two minutes after mixing serum with antigen dilution.

Briefly the test is performed in the following manner. The blood serum is inactivated in a water bath at 56 c for 30 minutes. Into three tubes are placed 05 0025, and 00125 c c of antigen dilution. Then to each of the three tubes are added 015 c c of inactivated blood serum.

worse on climbing stairs, weakness in the legs was a frequent accompaniment of this pain. A similar sensation was experienced after a heavy meal. Physical examination yielded no special information except bad teeth and muffled heart sounds. There was no evidence of emphysema (this must always be searched for in order to attach significance to muffled heart sounds). His blood pressure was 140/80, there was some evidence of arteriosclerosis in the fundi oculi. On being told the probable nature of his disease which I then believed to be coronary sclerosis he was skeptical and disappeared from observation. Subsequently, he returned and told me that several physicians pronounced his heart to be perfect. He was treated for rheumatism, dyspepsia, and gall stones. He subsequently developed all the classical signs of coronary occlusion including leukocytosis and pericarditis. He died suddenly, January 17, 1927, with an attack of coronary occlusion.

Case 2—W. P., age 47, storekeeper, came under observation in August of 1926. He gave a history of having been treated for stomach trouble which was rather persistent. Questioning yielded the information that there was no relationship between his indigestion and the ingestion of food. Various dietary modifications gave him practically no relief. His present attack began 11 days previously with pain in the epigastric region which did not radiate. The pain was gnawing and pressing in character and became worse after a full meal or exercise. A strict milk diet and medicine prescribed by another physician gave no relief.

The physical examination revealed the following. His expression was anxious, his temporal arteries were visible and moderately sclerosed. His heart sounds were distant, there was no evidence of enlargement on percussion. Blood pressure was 155/80. He was put to bed and was given nitroglycerin. His dyspepsia promptly disappeared. His blood pressure came down to 120/80. At present he is very comfortable except when he attempts to walk any distance or when he overfills his stomach.

Case 3—Mrs. S. F., age 41, came under observation December of 1925, complaining of repeated fainting spells and weakness for the past month. Her previous medical attendant diagnosed her case as hysteria. Careful questioning revealed that she had been having a dull ache in her precordium for about six months. This pain was aggravated by work or worry. The examination disclosed a woman rather anxious in appearance, afraid to move in bed, with pale cyanotic lips. In addition there was some mottling in her lips and forehead. Her heart sounds were hardly audible. Her blood pressure was 90/70. I kept her in bed for a number of weeks. She has since had several attacks of angina pec-

toris so diagnosed by two different physicians who were called in the early hours of the morning to aid her. Undoubtedly, the fainting spells that she had in December of 1925 were due to disturbances in the coronary circulation.

Case 4—Mr. S. A., age 66, realtor, came under observation in May of 1919. He complained of pain in his precordium and epigastric region. These attacks of pain usually came on about one o'clock in the morning. He was wont to retire about 11 o'clock, at which time he was accustomed to take a sandwich and a glass of milk. He attributed his attacks of pain to his constipation and disturbed digestion. Careful observation revealed that he would get attacks of pain on attempting to walk rapidly or following a day of worry and excitement. I observed him in the hospital for a period of three weeks during which time complete and thorough investigation of his gastro-intestinal tract was made. No abnormalities were found. Various dietary restrictions were of no avail. Complete rest in bed, however, together with large doses of bromides gave him almost complete relief. During his stay in the hospital I was fortunate in being present and witnessing one of his attacks. His appearance was so characteristic that I was able to make a diagnosis of coronary disease. In 1921 he had an attack of pain in his epigastric region which was diagnosed cholelithiasis. He was removed to a hospital for operation, but he declined consent. In 1923, while in the country he had more pain and the medical attendant at the time made a diagnosis of carcinoma of the stomach. Early in 1925 he had a typical attack of coronary occlusion with leukocytosis, tachycardia, fever, pericarditis and cadaveric appearance from which he recovered. He succumbed in June of 1926 to a similar attack.

Case 5—Mrs. H. K., 61, housewife, married, came under observation in November of 1923. She complained of pain in her left wrist and pain in her back in and about the angle of the left scapula. This pain was associated with definite nausea and would come on more particularly after walking or carrying of weight. She gave a history and had some of the physical signs of an old tuberculosis lesion in the left upper lung. I was, therefore, loath to make a diagnosis of coronary disease until activity in her lung with pleuritic pain could be ruled out. Examination of her sputum was negative repeatedly. Sometime subsequently she developed a very sharp attack of pain in her precordium which radiated to her back and into the left axilla. Associated with this there was pallor and sweating limited to her chest and neck. (This is a very interesting vaso-motor phenomenon in this disease.) She has since developed typical syndrome of coronary disease. She is unable to

### THE NEW OFFICIAL YEAR

The close of the Annual Meeting of the Medical Society of the State of New York was marked with the assumption of their duties by a new set of officers and committeemen yet the change is not violent and the affairs of the Society will go on without a change of policy for the personnel will not be greatly changed. There will be a rearrangement of duties and a broadening of work but the activities of the State Society have become so comprehensive that there is need that

every officer who has completed his term of duty should be ready to continue in the service and to give the society and the public the benefit of his experience. There is also need for additional officers and committeemen, who may be found among the workers in the County Medical Societies and District Branches. Enlistment in the activities of the component societies will find its fuller fruition in the broader field of the State Society.

JAMES E SADLER

The tubes are then shaken vigorously for two minutes and then 0.5 c c salt solution is added to each tube after incubating for 15 minutes. Again shake for several seconds. The tubes are then allowed to stand at room temperature for about five minutes when they are ready for reading.

It should be said here that the test is reliable only when performed by a competent serologist. Although it appears to be very simple it is not an office procedure.

The advantage of this test over other precipitation tests and the Wassermann reaction are that if there is the slightest suggestion of error the test can quickly be done over again. There are no chances of bacterial contamination interfering with the readings which sometimes result from long incubation, in emergency cases such as blood transfusions, it is of utmost value to the clinician, more so than the Wassermann can ever be. The quantitative test cannot be applied to all sera coming to the laboratory for examination only those giving four plus reaction with the routine test. The results of this procedure indicate the relative number of syphilitic reacting substances in the serum. It can readily be seen that some sera have a greater number of syphilitic reacting units than others. Some precipitates larger than others are commonly seen in four plus reactions. In other cases they are more flocculent in appearance. The serum in a given case may show for example 200 reacting units before beginning treatment and 40 units after the completion of the course of treatments. The routine test would still be four plus, the reduction from 200 to 40 units being a helpful guide to the physician.

Kahn (1) has determined the unit of reaction in the following manner. Complete precipitation resulting from 0.15 c c serum with 0.0125 c c standard antigen dilution as a constant with varying dilution of a given syphilitic serum with salt solution, the number of reacting units are determined by multiplying the maximum dilution giving a definite precipitate, by four. If 1:50 is the highest dilution in which a serum gives a definite precipitation, the serum contains 4 x 50 or 200 units.

The comparative findings between the Kahn test and the Wassermann reaction as observed by different workers is intensely interesting. The majority of sera showing disagreement are either very early cases, neurosyphilis, or old treated cases. Kahn (1) reported comparative findings on 101,200 sera. 43,030 tests performed by his earlier method showed 94.17%

absolute check, 5.08% relative check, and 0.74% showed no check. The remaining sera or 58,170 performed by his present method showed an absolute check of 97.64%, a relative check of 2.15% and no check in 0.21%.

Houghton, Hunter, and Cajigas (2) in their communication reported 13,971 comparative Kahn and Wassermann reactions. Of this number 898 were positive with both the Kahn and Wassermann, 11,801 were negative with both tests and there were 56 disagreements.

Schiff (3) reporting on 266 comparative tests found major disagreement in 24 or 9%. These were old treated cases with the exception of four which were primary. It has been observed that the Kahn test is more sensitive than the Wassermann in treated cases and in the primary stage of syphilis.

Our own series of 359 tests compared with the Wassermann results from the State Laboratory at Albany show 339 or 94.42% agreement and 20 or 5.57% disagreements.

Three of the sera showing disagreement were positive with the Kahn and negative with the Wassermann reaction. One was a case of neurosyphilis which had been treated, one was a primary case of syphilis and on the other no data was obtained. The remaining seventeen sera were negative with the Kahn and positive with the Wassermann reaction. Seven of these were old treated cases, three were cases of neurosyphilis which had received treatments, two were primary, one showed no clinical indication of syphilis, while no history could be obtained on the remaining four sera.

#### SUMMARY

The Kahn test is a practical precipitation test. It is reliable when performed by a competent serologist. The majority of discrepancies between the Wassermann reaction and the Kahn test occur in the treated cases. The Kahn test is slightly more sensitive than the Wassermann in treated cases.

## THE AMERICAN MEDICAL ASSOCIATION

The New York State Delegates to the American Medical Association report that the national meeting in Washington, like the state meeting in Niagara, was characterized by harmony and action.

The daily papers gave an unusual amount of space to the proceedings. One issue of the New York World, for example, contained four separate articles on various subjects that were under consideration by the Association. Among them was an excellent report of the action in regard to prescriptions for alcohol.

The Association had stated the general principle that Congress was exceeding its authority when it limited a physician in the use of any therapeutic agent, and that physicians should be free to prescribe alcohol according to the needs of their patients.

The date of publication of this issue of the Journal comes too early to permit of printing an account of the national meeting, but an outline of the actions taken will appear in the June fifteenth issue.

---

## A NEW TEST FOR DRUNKENNESS

The JOURNAL has called attention to the need of scientific research into the nature of alcoholic intoxication, and the development of tests for drunkenness which can be used by average physicians. The daily newspapers have stated that such a test was reported at the meeting of the American Medical Association by a worker from the University of Cincinnati. He devised a rapid method for determining the percentage of alcohol in the breath collected in a rubber bag, and he correlated the percentage with the results of psy-

chological tests made on the patients. He had examined more than five hundred persons whom the police had suspected of having alcoholic intoxication, and his results seem to indicate that the amount of alcohol in the breath indicates the degree to which the brain is affected by the alcohol. If the experiments and findings are confirmed, and a chemical test for mental incapacity is developed, the legal procedure in cases involving intoxication will be simplified and placed on a scientific basis.

---

## LOOKING BACKWARD

### THIS JOURNAL TWENTY-FIVE YEARS AGO

*'The Principles of the American Medical Association'* Time has abundantly justified the prophecy contained in the following editorial from the June 1902 issue of this Journal:

"Nations, governments and societies owe their stability, strength and progress to the association of individuals whose aims are worthy, whose aspirations are high, whose designs are wise and whose purposes are steadfast, who thus may hope to reach the goal of their ambition and win the object of such organization."

"How does the American Medical Association respond to this test?"

"1 Worthy Aims. The union of all the members of our noble profession of every State and Territory in a representative society for the scientific study of all that relates to our profession, the public welfare and the nation's

good, as well as the cultivation of social good fellowship."

"2 High Aspirations. The attainment of the highest ideals in medical education and practice, and the application of the 'golden rule' in dealing the one with the other."

"3 Wise Designs. The presentations at the annual meeting and through the columns of the Journal, free from all sectarian narrowness, of the results of individual efforts and the latest progress in our arts."

"4 Steadfast Purposes. The indefatigable pursuit during the past fifty-four years of these ennobling precepts has added constantly to our numbers and influence, and advanced our knowledge and the scientific character of our work which is studied and assimilated by our brethren throughout the world."

## REFLECTIONS ON THE ANNUAL MEETING

One of the duties of the editor is to report impressions gathered in the corridors of the hotels and the lobbies of the meeting rooms. Every officer and committeeman was besieged with questions concerning every conceivable phase of his activity. It was gratifying that usually the questions could be answered by reference to some report or article that had appeared in this Journal, for the Journal is becoming more and more the organ of the Medical Society of the State of New York, in fact as well as intention.

The annual meeting affords the opportunity for getting information of the affairs of the society, and inquiries were heard as to why certain measures were not brought up for discussion, for example the activities of the Committee on Public Relations. The obvious reply of course is that the activity is new and the field is broad, and controversial, and moreover the whole subject is in the stage of development and investigation. Moreover, the subject is covered in the annual report of the committees and officers. Still the suggestion was heard that it might be well to have a general session in which two or three committees might present the broad principles of their work.

Another question that was frequently discussed by groups in the lobbies was the annual banquet. The attendance this year was only about 150, many of those present being women. The question was asked "Does it pay to have a banquet when it is attended by only ten per cent of these at the meeting?" While it is true that a dinner is one of the best promoters of enthusiasm, yet there must be an occasion for it and a special end in view, which seemed to be lacking at the banquet in Niagara Falls.

The same question was asked concerning the annual meeting that was held on Wednesday evening. Although a large auditorium seating a thousand persons had been provided, the total attendance was less than forty, including a dozen ladies. The question was naturally asked "Why go to the trouble and expense of obtaining a large hall and securing noted speakers, when so few members care to attend the meeting?"

The charter of the society requires that one annual meeting be held, but there is no restriction as to its time or nature. The suggestion was heard that the society revert to the former custom of holding the annual meeting immediately after the adjournment of the House of Delegates. This would put it in its natural time at the opening of the general sessions of the society.

A successful innovation at a state meeting, was the smoker and entertainment given to the commercial exhibitors. The meeting developed an unexpected cordiality on the part of the manufacturers and dealers, and elicited words of unaffected praise for the friendly attitude of the officers of the State Medical Society toward advertisers. Physicians are dependent on instrument makers and drug manufacturers, and the Journal is dependent on commercial advertisers for a large part of its income. Doctors want the help of the commercial men, and the business houses must have the good will of the physicians. It would seem to be the most natural thing in the world that the two groups should get together in close cooperation, and it was a surprise to hear the advertisers say that the spirit of cordiality of the State Medical Society was almost unique in their experience.

The advertisers followed up their remarks with the practical suggestion that a section be arranged for the exhibitors. The tentative plan is that a meeting room be provided, readily accessible, in which the advertisers may demonstrate their wares by talks, lantern slides and clinical demonstrations. Each advertiser who wishes to make use of the room would submit a copy of his talk and a plan of his action, and would make his exhibit the equal of the scientific sections in ethics and literary quality. The talent to conduct an exhibitor's section certainly exists among the exhibitors, and competition among them will impel them to do their best.

The American Medical Association and some of the State Societies provide rooms in which pictures, both movies and stills, may be shown, and repeated as often as is necessary. The suggestion has been made that this feature be a part of the annual meeting. It could be conducted in the same room with the commercial exhibit section.

The multiplication of medical societies has become so great that a physician must often limit his attendance to those which are of peculiar interest and helpfulness to himself. There are national societies for specialists, and conferences of public health workers. The managers of hospitals meet to discuss their administrative problems, and voluntary health associations hold sessions which are designed to entice physicians. However, the fundamental medical organization is the county medical society, representing that specialty known as general practice. The last meeting of the Medical Society of the State of New York appealed especially to the family physician, for it emphasized those duties which are common to every doctor who practices medicine in any form.

Cultures were made of both initial and recurrent organisms, the latter constituting a transitory modification with a tendency to throw back to the original strain. It was assumed that the prompt disappearance of the organisms from the blood was due to the formation of an antibody. The author now attempted to arrest the disease before the first crisis by injecting immune serum, but this attempt was not successful, and he then resorted to injection of the serum in conjunction with the original culture. The fact that such inoculations did not take showed the great power of the serum in destroying the spirochete under these circumstances, although it was powerless to modify the fully developed disease. By persisting in these inoculations it was found that they did sometimes take. It was evident that antibodies introduced from without do not play the only part in destroying the spirochete, for the defense of the organism cannot be left out of consideration. It occurred to the author that these cases might be satisfactorily treated after the full development of the inoculated disease by combining the serum with neosalvarsan, so that while one agent reduced the virulence of the spirochete the other could the better attack the latter. This idea seemed to work out so well that the author believes he is on the track of a great discovery in the treatment of spirochetel diseases, especially syphilis. It was startling, he says, to see the positive results of the mixture when either agent given alone was inert.—*Muencheuer medizinische Wochenschrift*, February 18, 1927

**A Bacteriological Theory of Cancer**—In a letter to the *British Medical Journal*, January 8, 1927, 3444, J. Barcroft Anderson communicates the following authorized statement concerning the researches of Carl Spengler into human cancer. In 1909, Spengler isolated from four cases of recurrent inoperable cancer a Gram-positive bacillus which formed ovoid spores, and in the presence of body cells replaced the cell contents with these spores and so within the limiting surface of the body cell formed spore sacs. He had no doubt that this microorganism is an essential cause of cancer. He grew it upon somatose Beyer 5 grams, peptone Chapoteaut 5 grams, sodium chloride (pure) 5 grams, sodium carbonate crystals  $2\frac{1}{4}$  to  $2\frac{1}{2}$  grams, glycerin 50 c.c., water 1,000 c.c., with and without  $\frac{1}{2}$  per cent glucose and with and without agar. Last July he added to a pure culture of this bacillus on solid and in fluid media, after antiseptic treatment, the cells of pulmonary sputum, also the surface cells of the skin from the back of the hand, also a mixture of these skin cells and human blood. In every case he got proliferation of the cells, and after proliferation the cells were entered by the bacilli and spores were formed inside the cells, thus creating the appearance of spore

sacs. This change was most rapid and most pronounced with sputum cells. When this bacillus is grown in culture with human body cells, those cells tend to become Gram-positive. He knows of no other microorganism with which any of these results can be obtained. Since the commencement of these researches, Spengler has been treating cancer patients with immune substance taken from the blood of animals immunized with this bacillus, or with a vaccine made from this bacillus, or both. He now calculates on arresting cancer formation in inoperable cases within two weeks after starting treatment, and on getting rid of the tumor with further treatment.

**Antidotes for Corrosive Sublimate**—M. A. Rakusin recalls his earlier studies on this subject from which it appeared that charcoal, and especially wood charcoal, through its adsorptive properties is an efficient antidote to mercury in solution while magnesium hydrate is an antidote to arsenic and mercury alike, being superior in this respect to the oxide and carbonate of magnesium. Activation of wood charcoal by Zalinsky's method enhances its antidotal property. He has continued his efforts along these lines and has shown *in vitro* that wood charcoal can adsorb 95 per cent or more of sublimate, while others have placed the figure at 98 per cent. Apparently this is evidence that wood charcoal is the best antidote for sublimate and other quicksilver salts and probably can be shown to be of the same superiority for salts of other heavy metals. Other tests *in vitro* with conditions, such as blood temperature, conforming as closely as possible to those of the animal organism, showed that the adsorptive power of magnesium hydrate was much lower than that of wood charcoal while much more time was consumed in the process. Krawkow has recently claimed that magnesium is of equal value in poisoning with zinc and copper salts. In the antidotal use of adsorptive substances the latter must be given over and over again in contradistinction to the usual practice with chemical antidotes which are supposed to be given once for all at the earliest possible moment.—*Muencheuer medizinische Wochenschrift*, February 25, 1927

**The Nature of Lead Poisoning**—P. Schmidt emphasizes our lack of exact knowledge of this subject. There are two basic types, in one of which lead fumes are taken directly into the general circulation through the lungs, while in the other the metal is absorbed in the intestine and must traverse the liver before reaching the systemic circulation. There are four cardinal symptoms of plumbism, viz., the lead line on the gums, the color of the skin, basophilia, and porphyrinuria, and yet we find lead workers who are ap-

# MEDICAL PROGRESS

**The Nature of the Glossitis in Pernicious Anemia**—J P Schneider and James P Carey (*Minnesota Medicine*, April, 1927, x, 4) have verified Hunter's clinical observations on the tongue phenomena in pernicious anemia by applying the biopsy method, making the same histological observations that he had made in the dead. These studies show that mucosal lesions of all degrees of severity exist, from papillitis to necrosis and atrophy, that in the neighborhood of the active lesions there is small-celled exudation, and proliferation in the tissues and walls of the vessels, that the mucosa and submucosa harbor streptococci "staining badly with Gram's." In a total of nine biopsy specimens from eight patients ill with pernicious anemia, studied by the authors, all yielded *Streptococcus viridans* in pure culture, while in five controls streptococci were absent. These findings suggest strongly that this organism is responsible for the anemic lesions of the tongue during life. That the anemia *per se* does not act as a predisposing or favoring factor for the secondary invasion of the tongue is readily determined by the simple clinical observation that the tongue symptoms are antecedent to the anemia. Furthermore, during the course of the anemia it is a recurring observation that a glossitic attack will precede for a week or ten days a drop in the blood values. Schneider during the past twelve years has studied 450 patients with pernicious anemia, many of whom are still under observation, and is conducting further studies as to the rôle of *Streptococcus viridans* in this affection.

**Notes on Sickle-Cell Anemia**—George S Graham (*Journal of Laboratory and Clinical Medicine*, March, 1927, xii, 6), like other investigators, has never found this anomaly in persons other than full-blooded or part-blooded negroes. It may be found in individuals who are well and strong and in whom it is the only abnormality of the blood. In the majority of patients, however, the common symptoms are anemia, general bodily and mental underdevelopment, epigastric pain, low grade gastroenteric disturbances, muscular or arthritic pain, greenish coloration of the sclera, and sometimes general lymphoid enlargement. There may be slight enlargement of the liver. The urinary findings are usually low specific gravity, albuminuria and possibly cylindruria. Urobilin is usually present. Bilirubinemia is common in well developed cases. It is of particular interest that exacerbations of the an-

emia may follow exposure to cold or dampness, they may perhaps be brought on by overexertion. Patients with this type of anemia are peculiarly liable to respiratory tract infections. The blood findings are usually an elevated white-cell count, a few myelocytes, eosinophilia, and, during exacerbations, a high percentage of reticulocytes with large numbers of nucleated red cells. Phagocytosis of the red cells by circulating endothelial leucocytes is common. Among the author's 58 patients only two were over fifty years of age, the majority being in the second and third decades. Among 608 medical, surgical, and obstetrical patients in the colored wards of a county hospital the anomaly was demonstrable in 72 per cent. In an earlier series of 250 patients 52 per cent were "sicklers." Sydenstricker found an incidence of only 0.25 per cent. This discrepancy is probably due to the fact that a thin coverslip may elicit sickling while a thick one fails to do so. Graham did not observe sickling in red cells that had been received into large volumes of various isotonic solutions, when set up in high dilutions. The red cells have an increased resistance to the hemolytic action of hypotonic salt solutions. Their sedimentation rate is undoubtedly increased. Chemical studies of the blood showed the nitrogen values to be normal, the chlorides (calculated as sodium chloride) showed an average of 501 mg per 100 cc of blood, calcium averaged 8.33 mg, inorganic phosphorus ranged from 2.04 to 6.45 mg. There was an increased cholesterol value, which contrasts with the lowered values found in other anemias. Graham claims that there is need for some word to demonstrate the presence of sickling without committing one to any decision on the question as to what other morbid changes may have made their appearance in a given case. To fill this need he suggests the term "meniscocytosis," derived from the Greek word for crescent or sickle. Sickle-cell anemia seems to be related to hemolytic jaundice.

**Combined Therapeutic Use of Arsphenamine and Immune Serum**—W Krantz claims to have obtained astonishing results with this combination in animal experiments. He inoculated healthy mice with the spirochete of relapsing fever and showed that this organism at first multiplied in the blood to a sort of crisis, after which it vanished from the circulation but only to return in a recurrence. From two to four of these recurrences appeared during an interval of 30 days.

thermore, fibrillation may result from physical strain in hearts that are apparently normal, so far as can be determined by ordinary clinical methods. The medicolegal significance of this is of considerable practical importance. In one of the cases cited, it was claimed that the man broke down in consequence of the strain of his employment. The legal opinion given was that, "If a man, in lifting a weight or trying to move something not easily moved, were to strain a muscle, or rick his back, or rupture himself, the mishap, in ordinary parlance, would be described as an accident." This man strained the most important muscle in his body—his heart—and his auricles fibrillated. He was awarded compensation for total disability.—*British Medical Journal*, March 26 1927 3455

Treatment of Achalasia of the Cardia (so-called "Cardio-spasm")—Arthur F. Hurst, writing in the *Lancet*, March 26, 1927, ccvii, 5404, states that since it is impossible to restore the power of relaxation to the closed cardiac sphincter, the object of treatment must be to dilate it to such an extent that it no longer offers any resistance to the passage of food into the stomach. This can be done with the least discomfort and danger by means of mercury bougies. Rubber tubes of Nos. 28 to 34 gauge, 31 inches long, and each containing 1 lb 5 oz of mercury, which has been found by experience to be sufficient to force the closed sphincter, are now obtainable. It is best to pass the bougies on the first occasion during the x-ray examination. A mark should be made on the bougie at the level of the teeth when its two lower inches are within the stomach. Successively larger tubes are passed at a single sitting, and in most cases the largest one meets with as little resistance as the smallest. The patient is then instructed to pass the largest tube on himself before each meal. For the first few days the bougie should be retained in position on each occasion for as nearly a quarter of an hour as possible. After the passage of the tube the meals usually enter the stomach without difficulty. The time is reduced before lunch and dinner, and often, within a week, the midday passage can be given up entirely. Later the bougie is passed in the morning only, and the time it is kept down is steadily reduced. In favorable cases the bougie is passed only on alternate days then once a week, and then its use is discontinued. In one case in which the passage of the mercury bougie did not give sufficient relief, the sphincter was divided longitudinally, as in the Rammstedt operation for hypertrophic pyloric stenosis in infants. This patient was well three years after the operation. Hurst thinks that had the larger bougie now in use been passed surgery would

have been unnecessary. During the first week of treatment four meals a day should be given, each consisting of one pint of milk, which may contain a beaten-up egg. As esophagitis is likely to persist for a time, the diet should contain no pips, skins, or vegetable fragments. The patient should chew his food thoroughly, eat slowly, and finish each meal by drinking half a pint of water or milk to wash all traces of food into his stomach.

The Early Recognition of Tabes Dorsalis—E. W. Applebee, writing in the *Medical Record and Annals*, March 1927, emphasizes the necessity of making a diagnosis of tabes dorsalis in the pre-tabetic stage, as it is only during this stage that treatment can be said to be curative. In the great majority of tabetics there is a prodromal period of from two to five years, during which the classical symptoms are absent, and the patient complains of diffuse aching pains, which are usually diagnosed as either rheumatic or neurotic. In every case of obscure pain in an adult, tabes should be thought of. The diagnosis of neuritis should never be made if two weeks after the onset there are not some cardinal symptoms of neuritis—muscular atrophy, sensory changes, hyperactivity followed by diminution of the tendon reflexes, tenderness of the nerve trunks, or electrical reactions of degeneration. In the early stages of tabes careful examination shows a slight difference in the size of the pupils or a little irregularity in their outline, accompanied by what is inaccurately described as a sluggish reaction to light. The reaction is never sluggish, but the syphilitic pupil often requires a greater intensity of illumination in order to cause its reflex contraction. Other early signs of tabes are a diminution and loss of the vibratory and the deep pain sense and a disappearance or diminution of the ankle jerks. The loss of deep pain sense is characteristic, and its accidental elicitation during any physical examination should arouse suspicion. For example, if broken bones can be manipulated painlessly, or if manipulations within the urethra or rectum which normally cause distress, are painless, or if the dentist discovers that the patient is insensitive to the drill, the probability of tabes should immediately suggest itself. Diffuse pallor of the optic disc, even in the absence of amaurosis, is often found in tabes. Frequently failure to recognize tabetic crises has been responsible for unnecessary operations for supposed gastric ulcer, gall-bladder disease, or appendicitis. It is helpful to remember that in the tabetic crisis light touch causes intense pain, while firm pressure is well borne, the exact opposite of what occurs in acute abdominal conditions.

parently in good physical condition who present all four of them. The slow accumulation of lead in the alimentary canal is responsible for an entire series of symptoms comprising loss of appetite, belching, bad taste in the mouth, colic, etc. Lead is first an irritant, later a destructive agent. After it has reached the blood in certain amounts we see another train of symptoms, comprising anemia and spastic contraction of the arterioles. The latter may be present in the absence of anemia and is responsible for the peculiar greyish or yellowish tint of the skin. The deposit of lead granules in the capillaries and precapillaries is followed eventually by angiosclerosis, especially if there is already a tendency to that condition. If the kidneys are intact the lead is eliminated, consequently, as has long been known, it is the subject of renal insufficiency who is menaced with plumbism, in the case of those subjects who are healthy despite the "four cardinal symptoms" their immunity is due to the excretory efficiency of the kidneys. The best prophylaxis against industrial plumbism, Schmidt holds, is the weeding out of a large class of workers who present chronic alcoholism, disease or functional inferiority of the nervous system, arteries, kidneys, or the blood, syphilis, polyarthritis, and in fact the great majority of chronic diseases.—*Klinsche Wochenschrift*, February 19, 1927

**Treatment of Hay Fever by Diathermy**—Hamm anticipates the hay fever season by announcing his success last year with diathermy in the treatment of 20 cases (*Klinsche Wochenschrift*, March 19, 1927). There was not a single failure and the duration of the treatment was relatively brief. It is true that the wet summer of 1926 was somewhat more favorable to hay fever patients than previous hot and dry summers. Most of the patients had suffered from five to eight years, had tested many remedies with more or less success, and were good judges of their malady. Thus far no patient has required over five sessions of diathermy and in one case only was it necessary to anesthetize the nasal mucosa. What is the rationale of these results? The high tension alternating current on entering the nostril is changed to heat which may reach 40° C (104° F). This must result in a destruction of the pollen or in detoxicating it of the pollen toxin. In no other way can the sudden improvement be explained. The method ought to be tested in a large metropolitan clinic where it could be controlled with microscopic and chemical examinations. The frequency of the sessions was two a week, although Hamm has cured some cases in one sitting. He uses a special nasal electrode which before introduction is wrapped in zinc oxide plaster mull.

**The Gold Treatment of Ocular Leprosy**—Professor W. H. H. Hoffmann of Havana refers to the success of chaulmoogra oil as proof that leprosy is not incurable. The way is now open to the search for other remedies. Antimony in the author's experience and opinion may prove to be useful as an auxiliary. The value of gold in experimental tuberculosis and in clinical tuberculosis of the eye naturally suggests its use in leprosy, and the author has made a trial of it in leprosy of the eye which is a common lesion in the local leper asylum. It is evident that the first ocular lesions are in the conjunctiva and the disease extends by lymphatic propagation to the interior of the bulb. A large quantity of a gold preparation, to be used by injection only, was submitted for testing by a German drug firm. Madsen, the authority on the use of gold in experimental tuberculosis, does not believe that the metal exerts any bactericidal action but that it rouses the defensive forces of the eye. It is very evident that Nature always makes a determined fight against the lepra bacillus for the disease is eminently chronic with periods of quiescence, and various phenomena such as fever and allergic reactions also suggest a warfare between bacillus and natural defense. The author does not state how the injections are made but from analogy we may believe that they are subconjunctival. He has no doubt that they are efficacious for even after one or two injections improvement may be noted. Thus far he has seen no ill result from the treatment. Apparently only ocular leprosy has been treated with the gold preparation.—*Munchener medizinische Wochenschrift*, March 11, 1927.

**Trauma as a Cause of Auricular Fibrillation, Its Medicolegal Significance**—John Hay and Wallace Jones record five cases in which the advent of fibrillation might reasonably be ascribed to trauma or physical strain. They point out that the view generally held is that fibrillation as met in clinical practice, is always superimposed upon a preëxisting pathological change in the heart. While this probably holds good in the majority of cases, there are exceptions to it. In one of the reported cases the exciting factor was a powerful electric shock, in the remaining four the exciting factor was sudden physical exertion putting an unexpected and undue strain on the heart. In four of the five cases there was no evidence that the heart was diseased or abnormal, and up to the time of fibrillation the patients were living active normal lives. The authors hold that the evidence justifies the view that sudden strain may, and frequently does, initiate auricular fibrillation and induce cardiac failure in men and women with diseased hearts. Fur-

## MULTIPLE BREAST ABSCESES—PUERPERAL SEPSIS—DEATH

As administrator of his deceased wife an action was brought against a hospital and the house physician who at times had attended the deceased while she was a patient at the hospital

In this action it was charged that on the 17th of May the decedent had engaged the hospital for the purpose of providing her with a physician and hospital facilities wherein to be confined, that on the 20th of May she gave birth to a female child, that both the mother and child were under the direct care of the defendant physician, that the physician had failed to use proper care and skill in his attendance upon the decedent and that by reason thereof she developed an inflammation of the breasts causing inspissation of the milk and that the physician had likewise failed to use due and reasonable care in treating and caring for the inflammation, that without the consent of the patient or her husband an operation was performed upon the patient, that thereafter she developed a high temperature and delirious condition and became greatly reduced in vitality, and that while in such condition of high temperature and delirious condition the defendant physician had permitted and ordered the patient to be forcibly removed from the defendant hospital and that the hospital likewise had permitted, ordered and caused the patient to be forcibly removed, that because of the forcible removal of the patient and the negligence of the defendant physician the patient died on the 10th of June. Damages were sought to be recovered for the death of the patient and likewise by the husband for the loss of his wife's services

The defendant physician was a part-time house surgeon at the hospital. The decedent had applied to the hospital for prenatal care and arranged for hospitalization upon her confinement. She was first seen by the defendant physician about two months prior to her confinement, during which period she made three visits to the physician. At the April visits the physician had examined the decedent as to her pregnancy and found that she had a slight diabetic condition. He prescribed a strict diet and likewise advised the other necessary precautions for her condition.

The patient entered the hospital on May 16th at about 10 30 P. M., at which time temperature, pulse and respiration were normal. She was delivered of a normal female child in good condition at about 11 50 P. M. on May 17th. Prior to her admittance to the hospital and while under prenatal care the urine examination made on March 31 showed 0.4 sugar. A blood examination made on April 4th showed sugar 0.130 per cent.

The mother and child both progressed for a period of about a week, when the defendant physician discovered an abscess on the left breast and that the patient had a temperature of 103

degrees. At this time the defendant physician suggested to the patient that the mass be opened and later in the same day he advised her father of the patient's condition and told him that the patient would have to be operated upon, to which the father replied that the physician should go ahead. The defendant physician called the visiting surgeon in consultation, who after examining the patient and the mass of the breast, advised that the same be operated upon. Then, after taking the proper antiseptic precautions, sterilizing his instruments and likewise sterilizing the field of operation, with the assistance of the nurse the defendant physician, with a scalpel, incised the breast abscess. A large quantity of pus flowed therefrom. The wound was dressed with iodoform gauze and the patient left in bed. The operation was performed about noon time of May 29th. This incising of the abscess was the last treatment rendered by the defendant physician to the patient.

About two hours after the performance of the operation the patient's father by telephone advised the defendant physician that he was going to remove his daughter from the hospital. The surgeon advised against this procedure, but the defendant was insistent and procured a private ambulance and then removed the patient from the hospital.

The patient was taken to her home and later the same day a gynecologist was called in to attend the patient. Upon examination he advised her removal to another hospital. She was thereupon removed from her home to this second hospital, where the gynecologist continued to treat the patient. While at the second hospital the patient developed a series of abscesses first in the left and then in the right breast. The attending gynecologist incised the various abscesses at the proper time. The condition of the breasts became such that it was necessary to remove both of the breasts. After the removal of the breasts the patient kept running a high temperature and died a day or two after the breasts had been removed, her death being due to puerperal sepsis.

The surgeon who subsequently treated the patient was at a loss to determine the cause of the multiple abscesses and was of the opinion that the treatment of the defendant physician in no way contributed to the patient's death.

Both of the actions remained on the calendar for some period of time. The plaintiff being unsuccessful in his attempts to procure a settlement, motions were made on behalf of the defendant to dismiss the actions for lack of prosecution. After the institution of these motions the plaintiff, through his attorney, consented to the discontinuance of the actions, thus terminating them favorably to the defendant.

# LEGAL

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York

## THE ANNUAL MEETING

The one hundred and twenty-first annual meeting of the Medical Society of the State of New York was held in Niagara Falls on the first three days of the second week in May, 1927. It was an enthusiastic, successful and satisfactory meeting.

Promptly on the morning of May 9th the delegates assembled and were called to order by the Speaker. For two days the business sessions lasted and on Tuesday evening the annual dinner was held in the fine ballroom of the Hotel Niagara.

We doubt if ever in the history of the Society there was an annual meeting indicating a greater unanimity of purpose and a finer cordiality among the delegates. Perhaps more than ever, there was manifest a fundamental understanding of and a determination to carry out the purposes for which, during the administration of President Thomas Jefferson, back in the early days of the Republic, your Society was founded. Among those purposes there is that not only to federate and bring into one compact organization the medical profession of the State of New York but "to promote friendly intercourse among physicians."

If among those unacquainted with the medical profession there are any who believe that doctors, absorbed as they must be in the routine of their profession, are not conversant with prompt and efficient methods for the despatch of business, they would experience a sense of surprise as well as keen admiration could they observe with what a sound grasp and wise application of the rules of parliamentary law and procedure the meetings of physicians are conducted.

All the friends of your distinguished Speaker, Dr. E. Eliot Harris—and who that knows him is not his friend—rejoice that he could be present. In order to conserve the Speaker's strength, the vice-speaker, Dr. Harry R. Trick (your President-elect), performed many of the duties of the presiding officer, and did so with distinction and ability.

Throughout the day in the corridors of the hotel and in various impromptu excursions into Canada and inspection tours of the wonders of Niagara Falls, the doctors from all parts of the state met in friendly intercourse. George Leitner was ubiquitous with his unfailing repertoire of new stories, scattering sunshine on every group he met.

The annual dinner, held on Tuesday evening, marked the close of the business sessions. Dr.

Fisher presided and spoke gracefully and well, as did also the distinguished President of the American Medical Association, Dr. Wendell C. Phillips, and Dr. James E. Sadler, your new President. The dinner was followed by dancing to the accompaniment of an enthusiastic orchestra.

These annual meetings are of great benefit to the profession. They furnish not only a forum for the exchange of ideas, but an opportunity for the physicians of each section of the state to become acquainted with those from many others. If you counsel's feelings were shared by everyone and it is believed they were, all who were present took back to their homes memories of many pleasurable hours and a new zest and inspiration for carrying on the work of the coming year.

It is unfortunate that the lay public is not more aware of what fine human individuals the medical profession is composed. Could representatives of the lay public have been present at this annual meeting, they would have come away not only with a better understanding, but with a greater sympathy and appreciation for the men who carry on the daily battle against disease and death.

The writer in his experience has learned much about the practitioners of the healing art. One thing, however, which he did not before fully appreciate was the fine vocal gift possessed by so many of its members. At Dr. Fisher's luncheon the singing was such as to go down in the annals of music. We were not informed as to whether any representative of the Metropolitan Opera Company was present to sign up Dr. Orrin S. Wightman, but after having listened to the clear resonant high notes with which he favored us, we are all convinced that by his adoption of a medical career the operatic stage became a distinct loser. Dr. Dan Dougherty, blushing still from the ovation that had greeted his re-election, came in with a heavy bass.

To the writer it was a matter of regret that he could not remain over for the scientific session, but in the early hours of Wednesday morning it was necessary for him to wind his way to Buffalo to try a case.

No account of this meeting would be complete unless it contained some word of praise, well deserved, for the efficient and painstaking work of Dr. Schnell, the Chairman of your Committee on Arrangements.

left at the door of each visiting lady every morning as a greeting from the Medical Society of the County of Niagara. No one criticized the local committee for the regular morning rain, but everybody fully appreciated the way in which the clouds were swept aside on every afternoon while the visitors were entertained at golf and teas.

It is most pleasing to be assured that the people of Niagara Falls appreciated the visit of the doctors, as is shown by the following letters.

Mr. G. L. Bowe, Manager of the Convention Publicity Department of the Chamber of Commerce of Niagara Falls, writes to the Editor:

"May I take this opportunity to say that Niagara Falls feels they have had in the New York State Medical Society one of the finest conventions that ever met in Niagara Falls. Particularly do we feel that our city has been honored since it is our understanding that heretofore only seven cities in the State of New York have been capable of anywhere near successfully handling the Society's convention and I sincerely hope that what efforts this office may have put forth in connection with the convention arrangements have been helpful. I am sure it was a real pleasure to work with the different members of your Society and I trust that at the proper time the Society may wish to return with another convention to Niagara Falls."

The Hon. William Laughlin, Mayor of the City of Niagara Falls, wrote to the Chamber of Commerce:

"Conventions of this character I believe are of inestimable value to Niagara Falls. I heard many of our citizens comment upon the very high type and high class of delegates and visitors attending the meeting. Conventions of a scientific nature like this have a great educational value, and I hope that your Department may induce more such splendid organizations to come to Niagara Falls."

The informal social features of the annual meeting attract the members quite as strongly as do the formal sessions. The most vivid memories which one carries away are those of meeting old and new friends and a changing

views, humorous and serious, on all topics that interest doctors. The friendships formed at the meetings are the vitamins which infuse vigor and alertness throughout the great body of the medical profession. There is a compelling influence in a social luncheon which disarms suspicion and promotes interest in society affairs. The three or four social meals of which every member partook every day of the meeting were great factors in promoting the interest of the doctors in all phases of the practice of medicine.

Equally valuable were the semi-formal luncheons which were not announced on the programs. Dr. George M. Fisher, the retiring president, gave a social luncheon to his associated officers and committeemen on Wednesday afternoon, and the secretaries of the county societies dined with the officers on Thursday noon and agreed that a repetition of last year's conference of the secretaries would be desirable.

Of course, everybody saw the Falls from every point of view, except that most of the visitors had an unaccountable aversion to ride in the Maid-of-the-Mist. Yet the trip on the boat is more quiet and safe than that on a New York City ferry, and it reveals the height and grandeur of the Falls as does no other view.

The editor-in-chief and the executive editor yielded to their reportorial instincts by taking over five hundred pictures of the Falls, including several of the Secretary beaming benignantly upon bridal couples on Goat Island.

The registered attendance was 800 including 100 ladies, but since the general registration desk was in the Prospect House while the headquarters was at the Hotel Niagara, the attendance was much larger than the figures might indicate. The names of the officers and the members of the House of Delegates, some 150 in number, should be added to the general registration for they registered at the Hotel Niagara. Then too there were over 100 persons in attendance at the Commercial Exhibits. The total attendance at the meeting was well over one thousand.

## THE COMMERCIAL EXHIBITS

One of the most important features of a large medical meeting is its commercial exhibits. Physicians and manufacturers are mutually dependent upon one another and commercial dealers in doctors' supplies are as ethical as the medical men. The commercial houses are as anxious to show their products as the physicians are to see them.

There were thirty exhibitors at Niagara

Falls, and others would have shown their wares if there had been space for them. The exhibits were held in the Prospect House apart from the Niagara Hotel, which was the headquarters of the State Society. Yet the exhibit rooms were fairly well filled nearly all the time and those who came to see and learn were not distracted by an ever-changing crowd.

# NEWS NOTES

## THE ANNUAL MEETING

The One Hundred and Twenty-first Annual Meeting of the Medical Society of the State of New York, held in Niagara Falls on May 9-12, 1927, was characterized by quiet efficiency, and by action rather than talk. Few speeches were made, and none of them were long. No acrimonious debates occurred, and no factions developed. Some one remarked that the machinery of the Society had been well oiled. The fact is that the smoothness with which the sessions were run was due to the universal application of the Golden Rule. Disputes and debates have usually been between the representatives of two opposing groups,—the progressives and the conservatives. The differences between the two groups have been principally in the temperaments of their members. Some doctors are naturally conservative and have a veneration for the work well done by their famous predecessors. Other doctors are enthused with the modern spirit of progress, and are quick to advocate measures which involve changes in fundamental procedures long established. When the new proposals have been discussed on the floor of the House of Delegates, the inevitable results have been sharp clashes between the two temperamental groups. But no such clashes occurred during the last meeting for everybody seemed to have joined the ranks of the progressives, and were actuated with a sincere desire to see the medical organization grow and develop along natural lines.

The Annual Meeting reflected the very great growth in the development of the activities of the State Society and its component organizations during the past year. Probably no previous year can approach the last one in the interest universally shown in organized medicine, and the response of physicians to their civic responsibilities. Problems of a civic and community nature must be solved by the collective action of the group on whom the responsibility rests. Physicians are charged with the responsibility for the practice of civic medicine, and they have met it effectively by the action of their societies. The great item of progress during the past year has been to promote more intimate relations of physicians with official governmental bodies and voluntary health organizations and to develop agreements among all the varied groups of health workers as to the fields of activity which are peculiar to each. The crowning act of progress along civic lines has been the formation of a committee on public relations to adjust the fields of activity of the several health organizations, and to

make available the best medical advice to the community.

The progress of the past year had left few of the old topics of dispute. State medicine was a thing of the past, while health centers had died a natural death unmourned, and in their places there had been developed a system of conducting all forms of public health work by the concerted action of the trinity of health workers—the doctors, the departments of health, and the people themselves. Since the old sources of dispute have been settled spontaneously and amicably, there was small occasion for disputes in the House of Delegates, and the meetings of the State Medical Society were entirely harmonious, as all meetings are likely to be when effective action, rather than theory, is their basis.

The House of Delegates conducted its business with unusual celerity and smoothness. Every one recognized, for example, that the floor of the House of Delegates was no place in which to consider radical changes of the Constitution and By-Laws, such as the formation of a permanent committee on public relations. Half a dozen important amendments were introduced and will be acted upon at the session of 1928, and in the meantime, the discussion of their merits can be conducted in the meetings of the County Societies and the District Branches.

A great source of the debates and disputes in past years has been an ignorance of the work accomplished and planned by the leaders and officers of the State Society. Two factors have operated to remove that ignorance during the past year, first, the visits of the officers and committeemen to the County Societies and District Branches, and, second, extensive publicity in the JOURNAL. The officers have set a high record for visits to the component societies and the societies have outdone one another in welcoming their visitors. Then, too, there has been a greatly increased use of the JOURNAL in reporting the activities of all the organizations. The members of the State Society were well informed concerning its affairs when they came together in their Annual Meeting. The publication of the Annual Reports of the officers and committees in the JOURNAL before the Annual Meeting also contributed largely to the satisfaction which the members felt regarding the conduct of the Society's affairs during the past year.

The local Committee on Arrangements did its work well, and every physician and lady present was warm in praise of the manner in which they were entertained. A pleasing touch was a rose

## THE SCIENTIFIC SESSIONS

Most physicians who attend the meetings of the Medical Society of the State of New York are attracted especially by the scientific sessions. The scientific programs this year were unusually practical and of a high order of merit. The members of the Committee on Scientific Work, who arranged the program, were men of wide acquaintance among medical writers and speakers, and of wide experience in program making, and under the leadership of the Chairman, Dr S J Kopetzky, of New York City, they secured speakers whose papers were widely discussed and commended in the lobbies of the hotels,—a good sign of the value and popularity of the papers.

The program listed 106 subjects and 180 speakers,—a rather formidable list until one considers that they were distributed through nine sections besides the cancer exhibit, and over three days' time.

It is expected that the secretary of each section will secure the papers presented before his section, and will forward each one to the Editor of the Journal as soon as he obtains it, without waiting to get the entire list. Since there are one hundred papers to be published during the year in twenty-four issues of the

Journal, each issue should contain four papers, and their publication should begin at once.

There has been no provision for reporting the remarks of those who have discussed the papers. These discussions have often been of great value, especially in regard to new points presented in the papers. When a reader of the Journal sees a new idea presented, he at once wishes to know the opinion of others regarding it, and this information is often found in the remarks of the discussors of the papers.

The principal means by which an editor judges the authoritative standing of a paper is the attitude of the medical society before whom it is read. When the editor receives a paper for publication, he looks for the name of the society before whom it was presented. Frequently he will advise the author to present it before a recognized society, and will tell him that if the society will approve the article, the Journal will publish it. The remarks of those who discuss the papers are, therefore, of value, and it is hoped that the secretaries of the sections will ask the speakers to submit their remarks for publication in connection with their respective papers.

---

## THE CANCER DEMONSTRATION

Thursday, May 12, the last day of the meeting of the Medical Society of the State of New York, was given over to a cancer demonstration in three parts. First, there was an exhibit in the ballroom of the Niagara Hotel, including specimens illustrating the pathology of cancer, both gross and microscopic, demonstrations of methods of research on mice, and clinical lectures.

The second part consisted of moving pictures showing various forms of treatment and prevention.

The third part of the program consisted of four papers presented during the afternoon.

One great value of an exhibit such as that on cancer, and that on syphilis last year, is that it forms a vivid index which reminds the visitor of important points which he will study later. It is, therefore, planned to prepare a review of the exhibit and a resumé of the present status of cancer knowledge, and to publish them in a special cancer number of the Journal.

---

## THE ANNIVERSARY MEETING

The 121st Annual Meeting of the Medical Society of the State of New York was held in the auditorium of the Chamber of Commerce building, Niagara Falls, on the evening of Wednesday, May 11th, 1927. This meeting is more properly called the Anniversary Meeting, for that is the title used in the Act of Incorporation of the Society. There is no specified order for the meeting, and so in recent years it has taken a semi-popular form.

The members were welcomed to Niagara Falls by Dr Frederick J Schnell, Chairman of the Committee on Arrangements, and Dr Leo Wolf representing the Mayor of the City.

Dr George M Fisher gave the President's Annual Address, in which he reviewed the problems which the State Society is considering, among them being the nursing situation, cancer research, workmen's compensation, physicians for rural communities, rural hospitals, health education of the public by the newspapers, and the practice of preventive medicine. The address is printed as the first article in this Journal.

Dr Louis I Harris, Commissioner of Health of the City of New York, spoke on the present status of the practice of public health, especially the relations of physicians to the other

A feature that was unique and highly successful was a smoker and entertainment given to the exhibitors by the State Medical Society on the first day of the session in the Temperance House. Mr. Joseph B. Tufts, the Advertising Manager of the JOURNAL, arranged a short speaking program, followed by high class vaudeville acts and closing with light refreshments. About sixty representatives of the exhibitors were present, and all expressed themselves as feeling honored by the attention that was paid to them. The ladies connected with the exhibits were given a special supper in a room by themselves in the Prospect House.

Dr. O. S. Wightman, Editor-in-Chief of the JOURNAL, presided at a twenty-minute session which preceded the entertainment. The talks were brief and snappy, and were full of practical suggestions.

Dr. Frank Overton, Executive Editor of the JOURNAL, told of the policy of the editors and publication committee to assist the advertisers with their copy so that the quality of the advertisements in a literary and scientific way should be equal to that of the rest of the JOURNAL. He mentioned the tentative plan that the JOURNAL should have a department devoted to manufacturers and dealers in which the processes of production should be portrayed and the tests for purity and perfection be described. Examples of the proposed articles are the manufacture and sterilization of surgical ligatures, the manufacture of tablet triturates, and the standardization of digitalis products. No firm would be mentioned in the articles, but advertisements of the products described would be welcomed.

The speaker also said that the advertisers constituted a measure for estimating the popularity and value of the JOURNAL. The advertisers show their own appreciation of the JOURNAL by paying for space during the last year nearly double the amount of any preceding year, and for this the State Medical Society expresses its thanks.

Dr. George M. Fisher, President of the Medical Society of the State of New York, and Dr. James E. Sadler, President Elect, expressed their appreciation of the support given by the advertisers, and said that the Society would value any suggestion from them for making the JOURNAL a better advertising medium.

Mr. D. F. Storer, representing the John Curtiss Company, advertising agents, gave a brief talk on the subject "How Can the State Journal Help the Advertisers?" He said that the usual procedure of a medical journal was that when an advertiser makes an over-enthusiastic claim for his product, the Editor throws out the whole advertisement, whereas the Editors of the NEW YORK STATE JOURNAL

or MEDICINE will edit the copy and by a slight change of a line or two, will make the copy entirely acceptable. He said that the advertisers appreciate the friendly attitude of the JOURNAL toward the advertisers, and that they sincerely desire to be as accurate and scientific and ethical as the doctors themselves. He said that a continuation of the friendly suggestions by the editorial staff was the best service the JOURNAL could render the advertisers.

Mr. W. P. Schmid, Eastern Manager of the Cameron Specialty Company, gave his ideas regarding the exhibits at the Annual Meeting next year. He suggested that an exhibitor's section be formed, and a room provided in which the exhibitors could demonstrate their products according to a pre-arranged schedule. Each exhibitor would submit his written address for editorial review, and the Society would provide lights and stereopticons and other means of exhibition.

Dr. Robert Rasin of the Professional Service Department of the Dry Milk Company, New York, read a brief paper as follows:

"This courtesy, so unexpected, is however a pleasure, for it affords an opportunity to thank the Medical Society for this get-together which in my experience is unusual. This complimentary gathering is indicative of good fellowship and confirms a feeling that all of us are welcome guests of the New York State Medical Society."

"It has been stated that medicine has not kept pace with surgery, however, this statement is quite erroneous, for the most scientific minds and laboratories are employed by the various manufacturers, whether of drugs, chemicals, or apparatus, and have contributed wonderful opportunities toward the alleviation and cure of all ailments to which the human system is subject. We are further reminded of the fact that only such products as have been submitted to care and attention, prosper and prove worthy of the confidence and consideration of the medical fraternity at large."

"Now in regard to the question that has been put to me, What can the New York State Journal of Medicine do to help the advertiser? I would say, 'Closer personal contact with men representing the companies, closer contact with the exhibit representatives, help to extend good fellowship, and cooperation and professional courtesy to the professional service man.'"

Dr. Wightman, in summing up the talks, said that the suggestions would be presented to the officers of the State Society, and that he was entirely in favor of an exhibitor's section.

The Exhibitors' Meeting enabled the doctors and exhibitors to become acquainted with one another, and the exchange of ideas will be of great benefit to the Society as well as to the exhibitors.

program of social events especially for the ladies. The printed program, which was excellently carried out, was as follows:

Tuesday morning—Choice of rides to points of interest. Assemble in Lobby of Hotel Niagara, 10 A M.

Tuesday afternoon—Inspection of Shredded Wheat Factory, 2 P M. Bridge Tea. Shredded Wheat Auditorium, 2:30 P M. Table Prizes.

Tuesday evening—Banquet at Hotel Niagara, 7 P M. Ball following. Music by Colgate Isle of Blues Orchestra.

Wednesday morning—Choice of rides to points of interest or golf at Country Club, or visiting Power House and Paper Company. Assemble in Lobby of Hotel Niagara, 10 A M.

Wednesday afternoon—Ride to Fort Niagara, 2 P M. Assemble in Lobby of Hotel Niagara. Reception at Fort Niagara by Colonel Ingram and Company. Tea at Country Club, 4:30 P M.

Illumination of Falls each evening.

Your morning newspaper and rose convey the best wishes of our Organization.

Hostesses—Mrs. William H. Hodge, General Chairman; Mrs. W. A. Scott, Chairman Reception

Committee; Mrs. R. H. Sherwood, Chairman Automobiles and Rides; Mrs. Frank Guillemont, Chairman Registration; Mrs. A. M. Rooker, Chairman Shredded Wheat Bridge Tea; Mrs. N. I. Ardan, Mrs. E. E. Gillick, Assistants; Mrs. F. H. Towne, Chairman Golf; Mrs. Elbert Ingram, Mrs. A. A. Palmer, Hostesses; Fort Niagara, Mrs. E. L. Burhyte, Mrs. G. P. Eddy, Co-Chairmen Country Club Tea.

Assistant Hostesses—Mrs. C. G. Leo-Wolf, Mrs. Frederick Schnell, Mrs. Oscar Baer, Mrs. L. M. Jayne, Mrs. H. A. Creamer, Mrs. Glenn W. Arthurs, Mrs. John L. Bishop, Mrs. F. I. Clark, Mrs. O. G. Harrington, Mrs. A. J. Lawler, Mrs. D. F. Patchin, Mrs. I. M. Rieger, Mrs. P. J. Sciarrino, Mrs. I. M. Walker, Mrs. E. W. Henry, Mrs. C. A. Wisch, Mrs. R. C. Martin, Dr. Anna Vele, Dr. Beatrice Smith, Mrs. G. L. Miller, Mrs. Frederick Leighton, Mrs. W. Roger Scott, Mrs. Robt. C. Martin, Mrs. Raymond S. Barry, Mrs. Charles C. Childs, Mrs. H. C. Dumville, Mrs. J. B. LaDuca, Mrs. F. R. McBrien, Mrs. N. W. Price, Mrs. L. J. Rozan, Mrs. W. C. Steele, Mrs. O. F. Walker, Mrs. G. Welch, Mrs. R. A. Winslow, Mrs. J. V. Farruggia, Mrs. A. L. Chapin, Mrs. Frank Talbot.

## REPORT OF THE SPECIAL COMMITTEE ON PUBLIC RELATIONS

*To the House of Delegates*  
Gentlemen:

The undersigned, appointed under due authorization by the President of the Medical Society of the State of New York to meet with a committee appointed by the President of the State Charities Aid Association to consider problems arising on the common ground between medical practice and public health with a view to bringing about better understanding, and so far as practicable, harmonious action in the common interest of all concerned, are pleased to submit the following unanimous report:

Your committee met in New York, January 27, 1927, and considered in a general way the methods to be discussed and the policies to be adopted. It then went into session with the Committee from the State Charities Aid Association.

It was decided that the two committees should organize as a joint committee and Dr. George W. Cottis was elected chairman and Dr. Joseph S. Lawrence, Secretary.

The Committee held four meetings, each occupying the greater part of a half day. A Sub-Committee gave intensive consideration to the subject of county health units, and submitted a report which was accepted by the full Committee recommending the establishment of county health units and that the County Medical Societies should take the initiative therefore. The

Committee considered general problems with which medical practice and health activities are concerned and also considered a detailed questionnaire relating to many phases of concrete health activities and the relations of practicing physicians thereto.

### GENERAL CONSIDERATIONS

In view of the excellent progress in public health activities, and in view of the many benefits attributed thereto, it is generally agreed not only that present public health activities should continue unhampered, but also that they should be further developed in the future. For such activities to secure the best results, harmonious cooperation of all concerned is necessary. Heretofore and at present such harmonious cooperation has often been lacking with the result that health activities failed to accomplish their best results, and their effectiveness has been very often diminished.

Most of the basic principles upon which modern public health methods are carried on were established by the work of physicians. It is generally true that the success of public health activities has usually been in direct proportion to the interest taken therein by the medical profession. No other group has a better opportunity of studying public health conditions and health needs, no other group has a better opportunity for influenc-

two great groups of agencies in the public health field, departments of health, and voluntary organizations "Lay health organizations," he said "are vigilant to spur the doctor to better practice, and are eager to experiment with new procedures. They are, therefore, both a help and a challenge to physicians."

Speaking of the cults, Dr Harris said

"The people generally do not want chiropractic and other cult practices, and they go to them when the doctors fail to give relief. A great field of work of the voluntary organizations is that of protecting the public from the cultists."

In closing, Dr Harris made a plea that physicians in general practice assume the leadership that is rightfully theirs in all public health fields.

Edward J Harrison, Dean of the College of Arts and Sciences of Niagara University, gave an inspiring address on the broad influence of the physician beyond the limited field of his medical practice. "The doctor," he said, "is above the practitioner of other professions, for he deals with life itself. The doctor is held in high honor because he practices sacrifice and service. He recognizes a duty to give society a reasonable leadership in all matters of health and life. In order to fulfill his mission, he needs an education and experience much broader than that gained in all of science. He needs to know cultural and social subjects, such as are given in liberal arts course in colleges."

"A practical plan of medical leadership includes the emancipation of the people from three forms of slavery

"1 Economic, to show that financial reward is not the chief end of work nor the principal standard by which to measure usefulness

"2 Social, to free men from the thrall of propaganda which is the enemy of reason and deadening to the mind

"3 Emotional, so that men will be guided by reason rather than by their fleeting feelings

"The doctor is the inheritor of centuries of practice and research. His duties are social as well as medical, and what he says on any subject will be quoted. The public will support the leadership of the doctor if his outlook is broad and comprehensive."

Dr Wendell C Phillips, President of the American Medical Association gave a brief address in which he urged physicians to throw off their shackles of secrecy and teach the people the broad principles of preventive medicine.

Dr James E Sadlier, in assuming his duties as President of the Medical Society of the State of New York for the year, said that the leadership of ten thousand physicians was a great task which he approached with seriousness. He said that the time to talk was at the end of his term of office, rather than at its beginning, and he hoped that the next presidential address may include as many accomplishments as that of Dr Fisher.

## THE BANQUET

The Annual Banquet of the Medical Society of the State of New York was held on the evening of Tuesday, May 10th, 1927, in the ballroom of the Niagara Hotel. The after-dinner speeches were brief and pointed. The principal address was given by Mr William Ganson Rose, of Cleveland, who delivered a rapid fire of mingled wit and wisdom. The other speakers included Dr George M Fisher, retiring president of the Medical Society of the State of New York, Dr James E Sadlier, the incoming president, Dr Harry R Trick, President-elect, Dr Wendell C Phillips, Presi-

dent of the American Medical Association, and Dr Pusey, Past President of the Association.

Dr Frederick J Schnell, Chairman of the Committee on Arrangements, was toastmaster. He stated that he had invited the Medical Association of the Province of Ontario, Canada, to participate in the meetings of the State Society, and that he had just received word of the sudden death of the President Dr E Brandon, from blood poisoning.

An orchestra composed of Buffalo physicians gave a concert in the hotel lobby after the banquet.

## LADIES PROGRAM

The reputation of the annual meeting and the desire of the doctors to attend it are effected by the opinion of the visiting ladies, and their influence will be greatly increased when the Women's Auxiliary is formed, for one of the arguments in its favor is if that

will promote the sociability and attractiveness of the meetings of the State, District and County societies.

The local Committee on Arrangements anticipated the importance of the social features of the annual meeting by issuing a four-page

prevent misunderstandings and to promote the welfare of the people of the state

### APPENDIX A

Suggestions submitted by the Joint Committee of the State Medical Society and the State Charities Aid Association in regard to certain details of cooperation between practicing physicians and health workers in the conduct of health activities

#### 1 Tuberculosis

Tuberculosis clinics are necessary in most communities. In some localities the local practitioners can and will perform the necessary clinical services, in other communities they cannot. Until adequate local service is available, experts should be brought in. It is recommended that all County Medical Societies should consider organizing and carrying on post-graduate courses in tuberculosis.

In clinics where expert service is provided, local practitioners can render valuable assistance through proper cooperation with the expert, and such local practitioners should be remunerated from either public or private funds, depending upon local circumstances which can most advantageously be worked out with the cooperation of the County Medical Society.

Tuberculosis clinics should receive suspects and contacts referred by physicians or health officers, and also those making personal application. When a public health nurse discovers a suspect or contact case, she should receive the approval of the family physician before suggesting attendance at the clinic. If there be no family physician, the nurse may refer the case directly to the clinic. After the diagnosis of tuberculosis is made, the patient should be referred to a private physician when possible. Selection of physicians when there is no family physician should be left with whatever agency is conducting the clinic and the County Medical Society.

The medical director of the clinic, the public health nurse, and the private physician attending the case should cooperate to secure adequate and continued treatment, and the matter of developing cooperation to that end should be in the hands of the medical director of the clinic.

In the interest of public health, all cases applying to a tuberculosis clinic should be received for diagnosis, but no treatment should be offered except to patients who after investigation are found to be unable to afford the services of a physician.

#### 2 Mental Hygiene

Clinics for the detection of mental deficiency and mental disturbance are necessary and desirable. Local practitioners should be expected to assist, and should be invited to participate in such clinics and to bring patients.

After a diagnosis is made and treatment has been outlined at the clinic, such mental cases not

requiring commitment may generally be referred to private practitioners for treatment. Adequate and continued treatment calls for satisfactory cooperation between the clinic, the family physician and the public health nurse, and it is the duty of the clinic to seek and promote such cooperation.

#### 3 Pre-Natal Care as a Public Health Activity

The Committee recognizes the value of adequate pre-natal care, but feels that as a public health activity it is still in the experimental stage, and only the following statements are warranted at the present time.

*First* That the work is at present largely educational,

*Second* That the demonstration in pre-natal work that has been and is being carried on in Tioga county by the State Health Department, assisted by the Maternity Centre Association, and with the cooperation of the Medical Society of Tioga county, should be thoroughly reported to other County Medical societies,

*Third* In regard to pre-natal work, the Committee recommends that, after consultation with the County Medical Society, there should be established a public health nursing service, which will seek out the pregnant women of the community and if they are not already under medical care and observation, will bring them into contact with their physicians at as early a stage as possible.

#### 4 Welfare of Infants and Children of Pre-School Age

The Committee believes that, where there are a number of infants and small children in a community, who, either through parental poverty or ignorance, do not receive adequate medical and nursing care, it is desirable to have child health stations. When such child health stations are established, they should be carried on under the direction of local physicians, whenever feasible, with the assistance of consultants, if desirable.

The responsibility for the conduct of child health stations involves the County Medical Society, the local administrative agency of such station, and any other interested group.

As to whether child health stations should receive for purposes of examination and diagnosis only children of indigent parents, or should be open to much larger groups, the Committee recognized that conditions in this respect at the present time differ as between the larger cities in which expert pediatric service is available and the rural areas and smaller cities in which generally it is not. In rural areas and smaller cities where pediatric services are not available, the Committee recommends that child health stations be open to all children whose parents may bring them for examination irrespective of economic status. In the larger cities it recommends that such clinics should not receive for examination children of parents who are able to pay for such

ing the habits and modes of life of the public. For these reasons, and also because the work of the physician antedated that of health agencies, it is recognized that the physician has a very great interest in public health work, and that his activity in such work should be encouraged, and his cooperation at all times solicited.

All public health work should be undertaken with the assumption that the intimate relationship between physician and patient will not be disturbed, but will be encouraged. Voluntary health organizations should invite representation on their committees and boards from the organized medical bodies. New or drastic changes in the policies of such organizations should first be submitted to the representative medical organization for study and recommendations.

#### RELATIONS BETWEEN MEDICAL ORGANIZATIONS AND VOLUNTARY HEALTH AGENCIES

It is fully recognized that County Medical societies, and county and other local voluntary health agencies are fully autonomous, and that no direction nor control over them can be exercised by state-wide organizations. In order, however, that the results indicated above, as being desirable, may be as fully secured as possible, it is believed that certain suggestions may appropriately be submitted for consideration to local health agencies and medical societies, action on their part of course being strictly optional.

It is believed that effective relations in the public interest will be promoted if voluntary health agencies on their part will include the following steps in their program:

(a) Invite the County Medical Society to designate a certain number of its members, say two, to become members ex-officio of its board of directors or executive committee, if there be one.

(b) Lay its annual program of activities before the County Medical Society for information and suggestions.

(c) Appoint a special committee to confer with a similar special committee appointed by the County Medical Society about matters that come up from time to time in which both groups are mutually interested.

(d) Report to the parent body of the voluntary health agency any matter as to which an accord has not been reached with the County Medical Society, in the hope that through conference between the parent body of the voluntary health agency and the State Medical Society any such matter may be negotiated and adjusted to the mutual satisfaction of all concerned.

(e) Conduct at least one open meeting each year to which the members of the County Medical Society are specially invited.

It is believed that these desirable results will also be furthered if the County Medical Society will include the following in its program:

(a) Accept the invitation from the voluntary health agency to designate certain of its members to serve as members ex-officio on the board of directors or executive committee of the voluntary health agency.

(b) Study and consider any program of activities that may be referred to it by the voluntary health agency for information and suggestions, and, if such program is approved, make a public statement to that effect, and otherwise support the program so approved.

(c) Appoint a special committee on public relations to confer from time to time with similar committees appointed by the voluntary health agency on matters of mutual interest to both agencies.

(d) Report to the State Medical Society any matter as to which an accord has not been reached with the voluntary health agency, in the hope that through conference between the State Medical Society and the parent body of the voluntary health agency any such matter may be negotiated and adjusted to the mutual satisfaction of all concerned.

In approaching the subject of concrete health activities, such as clinics, etc., it is believed that the following general statements, accepted by all the members of the Joint Committee, may be placed on record:

1 In all communities there exists a large amount of illness and poor health which does not seek and, therefore, does not receive medical diagnosis and treatment, at least not at a favorable stage.

2 Important new discoveries and improvements in preventive medicine should be made available at the earliest practicable time to all persons seeking medical aid.

3 Sound public policy demands that for all persons, irrespective of residence, there should be available the essentials of reasonably good medical diagnosis and care when ill.

4 The continued economic security and well being of the medical profession is an essential factor in meeting the preceding conditions.

5 In all health clinics and activities, the service of local physicians should be utilized and remunerated, and special skill or services should be secured when needed.

6 In order to conserve the largest usefulness and economic well being of the medical profession, and at the same time to bring progressive measures for the protection of health to the population generally, and to interest the population generally in seeking medical aid both curative and preventive, it is highly important that definite understandings be reached between the medical profession and others also engaged in the promotion of preventive health activities.

Your Committee gave very careful consideration to numerous detailed questions arising in programs in tuberculosis, mental hygiene, and other subjects, and arrived unanimously at detailed suggestions thereon which are appended to this report. We recognize that public health activities, and in some degree the practice of medicine, must change in the light of experience and of new knowledge. We submit these detailed recommendations as offering in our judgment helpful suggestions at this time to local health agencies, medical societies, and practicing physicians in the establishment of efficient and harmonious relationships in the promotion of public health, and in the adjustment thereof to the long established ideals and practices of the medical profession.

The members of this Joint Committee are keenly aware of the importance of the subject which they have been asked to consider, and are gratified that no obstacles have arisen to prevent unanimous agreement after full and frank consideration of all the facts involved, and believe that the adoption of the above recommendations by the State Medical Society and by the State Charities Aid Association, will tend to facilitate the more efficient conduct of health activities, to

## OTSEGO COUNTY

The Semi-Annual Meeting of the Otsego County Medical Society was held in Coopers-town, N Y, on May 4th, at 5 P M The meeting was called to order by President F H Marx The minutes of the March meeting were read and approved

Dr James Greenough of the Bassett Hospital was received into membership Dr M H Atkinson, having moved to Catskill, asked to have his name transferred to Catskill

On motion the meeting to be held in September was voted to be held at Three Mile Point It was to be a clam bake and the physicians of Cooperstown were appointed a Committee of arrangements On motion of Dr Lang the ladies were to be invited to the bake On motion of Dr Champlin the Society of Chenango, Schoharie and Delaware were to be invited to join with us for this occasion

The matter of a County Laboratory was referred to a committee who should present the matter to the Board of Supervisors at their

next meeting Dr Greenough, Cruttenden, Atwell Mills and Champlin were appointed such committee

Dr Bissell having left the County and Dr Warren being unable to attend the State meeting Dr R D Champlin was elected to act as delegate for the meeting in Niagara Falls in May

After a dinner at the Fennimore, the members went to the Imogene Bassett Hospital where Dr H L K Shaw of Albany gave an instructive address on Malnutrition of children

Members present Drs Marx, Augustine Parish Mills, Cooke, Champlin, Lang, Smith and Brownell of Oneonta, Ford of Otsego, Warren and Winnans of Franklin, Craig of Davenport, Wakeman of Andes, Maurer of Margaretteville, Loomis of Sidney, F L Winsor of Laurens, Swanson of Springfield Center, Cruttenden, Atwell, Greenough, Mackenzie of Cooperstown Bolt of Worcester

A H BROWNELL, *Secretary*

---

## BROOME COUNTY

The Broome County Medical Society held its regular monthly meeting on Tuesday April 5th, at the Arlington Hotel at 8 30 in the evening After the usual business meeting, Dr Harry A Bray, Raybrook N Y, Medical Supt, N Y State Hospital for Incipient Pulmonary Tuberculosis, Raybrook, N Y, gave an address to the Society on "An Appraisal of

Certain Physical Signs in the Diagnosis of Incipient Pulmonary Tuberculosis," illustrated by lantern slides Dr Bray's paper was very interesting and instructive and was presented in a pleasing and scholarly manner An active discussion with questions followed As is the usual custom, a buffet luncheon was served to the members directly after the meeting

---

## A LETTER FROM DR STROGANOFF

Following his receipt of the January 15 issue of this JOURNAL containing the article of Dr Stuart B Blakely of Binghampton on Stroganoff's treatment of eclampsia and Russian posters on child welfare Dr Stroganoff sent Dr Blakely the following letter dated Leningrad February second

'Dear Colleague,

I thank you very much for your sending of *New York State Journal of Medicine* and with great pleasure I read your paper You wrote better than some one But you have some mistakes (1) I do not use "morphine sulfate" but "muriatic" (2) I give digitalis not at pulse rate 100 but 110 and over

All rest is beautiful

I read also upon your Annual Meeting at Niagara Falls, and with great pleasure should be there, if there was the question about eclampsia

Did you read last number of "Zentralblatt für Gynaekologie," (N 8, 1927)? What dreadful mortality from eclampsia in Germany (p 490), where they not apply practically my method And you lose yearly 5 000 mothers and about 7,500 children The strife with this disease has international importance. But as the governments, as the accoucheurs, make very little for the diminution of this dreadful mortality, although they speak very much about that I mean, if you lost yearly 5,000—12 000 cows, or horses your measures for diminution of such mortality would be more energetic

With kindest regards to you and your wife

Respectfull,

W STROGANOFF "

examination at the rates at which it is to be had locally

The interpretation of what constitutes treatment at child health stations should be left to the management of such stations and the County Medical Society

Proper hospital facilities for the care of sick children should be made available in all parts of the state

## 5 *The Control of Venereal Diseases*

Venereal disease clinics are essential for the diagnosis and treatment of cases of venereal disease in every community. As to how medical service should be provided, and as to whether local practicing physicians should participate in such clinics and, if so, on what basis they should be compensated, will depend upon local conditions

The Committee suggests that public health authorities might assist private practitioners in securing adequate and continued treatment for all cases of venereal disease by disseminating advice and information from the clinics, by the services of public health nurses for following up cases, and by the continued free provision of salvarsan

The Committee suggests that such clinics should receive all patients upon application and, later, through proper channels, investigate their ability to pay

## 6 *School Hygiene*

The organization and conduct of school medical inspection are provided for in the Education Law of the state. The statute covers the subjects of medical examination and diagnosis, and follow-up work by school nurses. With respect to treatment, the statute provides that the school authorities shall notify the parents as to the existence of defects and physical disabilities. If the parents or guardians are unable or unwilling to provide the necessary relief and treatment of such pupils, such facts shall be reported by the school authorities to the school medical inspector, whose duty it is to provide relief for such pupils

The Committee believes that all treatment should be performed by the family physician, that the school physician should submit to the parents the report of his findings, and that the parents should then be urged to have the treatment performed by the family physician or by some physician of their own selection

Respectfully submitted,  
 GEORGE W. COTTIS, *Chairman*  
 WILBER G. FISH  
 THOMAS P. FARMER  
 JOSEPH S. LAWRENCE  
 W. WARREN BRITT  
 TERRY M. TOWNSEND

May 1, 1927

## SENECA COUNTY

The semi-annual meeting of the Medical Society of Seneca County was held May 12, 1927 at Seneca Falls. The morning session convened at 11 o'clock, and was occupied by a business session. Dr. Robert F. Gibbs of Seneca Falls was elected to membership and Dr. Robert F. Knight, formerly with the State Health Department, was reinstated to membership

It was decided to inaugurate a summer meeting at the Seneca Falls Country Club, the first part of August. There is to be one scientific paper at this meeting, the rest of the time to be spent in recreational activities

The following members were nominated for office

For President, Dr. E. W. Bogardus, of Romulus, for Vice-President, Dr. W. M. Follette, of Seneca Falls, for Secretary and Treasurer, Dr. J. N. Frost, of Waterloo

Dr. F. W. Lester reported for the Legislative Committee and urged more of the members to take advantage of the Group Insurance plan for physicians. He called attention to the fact that Seneca County had the second highest number of nurses for its population compared with all the other counties of the State

Luncheon was held at the Gould Hotel. Following luncheon, Dr. S. A. Mumford of the Clifton Springs Sanitarium, spoke on the subject of "Cardiospasm and Its Relation to General Practice." He first spoke of the classification of patients into two types, vagotonic and autonomic and described types of each. He spoke of the vagotonic type as peculiarly likely to suffer from cardiospasm and to have frequent vague digestive disorders, which after other pathology was carefully ruled out, could be readily explained by the symptoms of cardiospasm

He then presented a number of cases with X-ray plates showing cardiospasm, detailed the type of treatment given these patients and spoke of their improvement under proper treatment. Some plates and histories illustrating differential diagnosis was also shown and explained. Dr. C. H. Jewett, Chief of X-ray staff of the Sanitarium, accompanied Dr. Mumford and explained the plates in detail. The paper was extremely interesting and very profitable to the general practitioner. The paper was discussed by Drs. F. W. Lester, George M. Brandt and A. Letellier of Seneca Falls, and Dr. T. M. Cole, of Romulus

But the 2,000 years of burial of Herculaneum are but a moment compared with the vast stretches of time which have elapsed since the first evidences of man were buried in the protecting earth. The *New York Times* of May 17 has a news item which tells of the discovery of pieces of bone which may have been fashioned by men millions of years ago. The article says:

"Pieces of bone, which may or may not have been fashioned by the hand of a tertiary primate but which curiously resemble implements made by the Aztecs at a much later date, were exhibited last night at the American Museum of Natural History by Professor Henry Fairfield Osborn with the explanation that they had been dug out of Pliocene fossil beds in Western Nebraska during the Summers of 1925 and 1926.

"If these bone objects were not the natural products of wind and sand action, Professor Osborn said, they must be construed as evidence that man lived in America in the Pliocene or at a period of from two to three million years ago.

"Professor Osborn wished to make it clear to his audience that the supposed bone instruments

may not be authentic and that opinion at the museum is at present divided. He said he had not made up his own mind as yet. 'But whether these Nebraskan fossil implements are genuine or not,' he said, 'there was a very long bone-tool making age all over the world antecedent to the flint-working age and subsequent to a still earlier wooden tool age.'

"In support of the ability of Pliocene man to fashion implements, Professor Osborn exhibited a series of flint rostro-carinates or 'beak-keeled scrapers' just received from the upper Pliocene beds of England through J. Reid Moir. He said it was fairly well established that man lived in England 1,250,000 years ago, but that most authorities have been convinced that man has dwelt in America for 10,000 years.

"A paper by Harold J. Cook was read at the museum meeting. In it Mr. Cook declared that recent discoveries in Texas and New Mexico of Pliocene bison skeletons containing spear points and arrow heads gave evidence that man must have lived on this continent at least several hundred thousand years ago.

---

## BRITISH BEER

The alcoholic question has many phases which trouble England as well as America. The *New York Times* of May 5 said editorially:

"By way of assault upon the Trades Union bill the British Labor Party has been invited to consider a six months' boycott on liquor and tobacco. The chief purpose is to hit Mr. Baldwin in his pocket nerve. The Exchequer derives about \$650,000,000 annually from excise duty. Even the ingenious and optimistic Chancellor Churchill would have to do some active scurrying about to plug up the hole if Labor decides upon the heroic remedy. But Treasury deficits are the least of the danger. An English nation deprived of its beer for six months is apt to de-

velop an utterly un-English ugly temper that bodes ill for the existing system.

British per capita consumption of milk is less than one-fourth of that in the United States. The British public consumes 700,000,000 gallons of milk, as against 960,000,000 gallons of beer, and the beer bill is highest where there are most children in need of milk. The Bermondsey section of London demanded in 1924-25 no less than 5,500,000 gallons of beer, but got along with 1,210,000 gallons of milk.

'It is, however, a national habit a couple of thousand years old counting from when British mead gave way to English ale and it is doubtful whether even the present high tide of party feeling can make a serious breach in it.

---

## VIVISECTION

The word vivisection, meaning cut up alive, carries a sinister meaning to the lay mind. Whatever animal experimentation may have been in the early days of science, it no longer bears the mark of cruelty, which has heretofore been the basic objection to the practice. But now there has risen a new class of objectors who wish to exclude dogs from experimentation on the ground that they are man's friend. The *New York Times* discusses this point on April 15 in the following editorial:

When advancement in science has demanded

it, even human beings have been willing laboratory material. While Dr. Walter Reed was developing the theory that yellow fever was carried by mosquitos, men volunteered for his tests. Many human lives have been sacrificed in the scientific battle against disease. It may be that people who feel that dogs should be exempted from surgical experiment are trying to let them off a job that the dogs themselves would be willing to take on. On occasion dogs have been willing enough to sacrifice themselves for their human friends."

# THE DAILY PRESS

## EMERGENCY MEDICAL SERVICE IN THE RURAL DISTRICTS

The New York *Times* of April 4 had a news item stating that the Grange of Genesee County had appointed a committee to confer with the Genesee County Medical Society regarding provision for obtaining the services of physicians in emergencies. The immediate occasion of the action of the Grange was the recent death of a boy whose mother was unable to obtain a doctor although she had called five during the night, and she lived only two miles from the city of Batavia.

It would not seem that this case is to be classed as rural. But whether it was rural or urban, the proper procedure was followed when the Grange, a lay organization representing the patient, appointed a committee to confer with the County Medical Society representing the physicians. This plan of action is that advocated by the Medical Society of the State of New York in forming its committee on Public Relations.

## CANCER RESEARCH

Judges on the bench are frequently divided in their opinions, and it is therefore to be expected that laymen should draw some unexpected conclusions regarding medical subjects. The New York *Herald-Tribune* of May 4 has printed a letter from a Brooklyn layman who says:

"You will recall Mr. William L. Saunders recently offered a substantial reward for any one who may discover a preventive and cure for cancer.

"At the time of the announcement Mr. Saunders said 'Discoveries are not always made by experts—physicians, like business men, are not always the best research workers.' The matter was placed in the hands of the American Society for the Control of Cancer, which organization sent me a form letter, the second paragraph reading 'The decision upon which these awards are made is to be determined by the American Society for the Control of Cancer and approved by the American Medical Association and the American College of Surgeons.' A layman stands

no chance in the world to impress this array of men.

"It is very likely the last named body will OK any program that does not embody surgery in some form? Doctors have steadfastly declared the only relief from cancer was a speedy operation—the sooner after discovery the better. The question of diet and the accumulation of material foreign to the body is scoffed at by this group as having anything in common with cancer, its cause, prevention or cure.

"Can these men, trained to wield a knife, honestly and sincerely serve mankind by acting as judges on this very vital problem?"

The correspondent has no conception of the vast amount of cancer research work that has been done in which diet and intoxications have been thoroughly investigated and found to have no significance in cancer. While the surgeon regrets that at present an operation is almost the only known remedy that offers a hope for the cure of cancer, yet he will be the first to welcome the discovery of a better means of treating the disease.

## MAN IN PAST AGES

It has often been said that interest in one's ancestry is a sign of old age. However, man today, physically and mentally, is almost identical with his ancestors, for he inherits their characteristics according to the strict laws of heredity. Certainly man has changed little during historic ages.

The New York *Times* for May 17, comments editorially on the proposed excavation of Her-

culaneum, the city of Hercules. Physicians will be interested in the revelations for they are expected to show the daily life of the people, and the sanitary arrangements of the homes to a far greater extent than the excavations of Pompeii, both of which cities were buried by an eruption of the volcano Vesuvius in the year 79 A.D. While Pompeii was buried under soft ashes, Herculanum was sealed in hard lava so that the contents of its houses are well preserved.

# BOOK REVIEWS

**THE PATHOLOGY AND TREATMENT OF DIABETES MELLITUS**  
Second Edition. By GEORGE GRAHAM, M.D. 12mo of 230 pages with 26 illustrations. London and New York, Oxford University Press, 1926. Cloth, \$2.75 (Oxford Medical Publications)

The general arrangement of the first edition has been followed in the second edition, the first part giving an account of the physiology of the sugar metabolism and the second describing the different types of diabetes mellitus and the treatment of the disease. Chapters have been added on the principles and details of treatment with insulin and many alterations made in the text to conform with new facts.

The ladder diet in use at St Bartholomew's hospital since 1915 has been adapted to the use of insulin. The author prefers this to the maintenance diet more generally used in the United States. The advantages claimed are simplicity and the ease with which variations can be made by the patient. Rest in bed is advised at the beginning of treatment for two weeks. There are ten diets ranging from a hunger day for two days to a diet of 1,562 calories in twenty days of P67 C48, F117. This last diet may be increased by 100 calories by adding 13 grams of protein and 5 grams of fat; this general plan is continued until a sufficient diet is reached. Woodvatt's method of estimating the ketogenic anti-ketogenic ratio is described.

The book is well written and of scientific and practical value.

W E MCCOLLOM

**HISTOLOGICAL TECHNIQUE** For Normal Tissues, Morbid Changes and the Identification of Parasites. By H M CARLETON, M.A., B.Sc., D.Phil. Octavo of 398 pages with 17 illustrations. London and New York, Oxford University Press, 1926. Cloth \$5.00 (Oxford Medical Publications)

Mr Carleton's book is an excellent and most successful attempt on the part of a brilliant scholar and teacher to alleviate the trials and struggles of those constantly confronted with the necessity for understandable information and ready help, by presenting his subject in a practical volume, couched in terms clear and concise and within the scope of the most humble lay technical worker or professional beginner.

Mr Carleton's book takes for granted that those who are about to read his book are in search of information which he dispenses in a masterly fashion and most generously, never misleading and always pointing out the simplest effective methods, and explains always in detail why he considers them so.

The book is introduced by a very clear and interesting description of "Living Matter—The Cell—Nuclear Components—Cytoplasmic Component—Theories of the Structure of Protoplasm—Tissues" then proceeds to give all the ways and means of preparing tissues for microscopical examination.

The "Table of Errors in Section Cutting and Their Remedy," also "Table of Faults in Dehydration—Clearing and Embedding" are of value to all interested in this work as they include problems and their solutions that can only be encountered and mastered by long practical experience. They are invaluable to the inexperienced and even the most skilled worker will find some new and helpful suggestion in the list.

If every beginner had access to such a book many discouraging errors and great loss of time would be avoided.

All of the most valuable Type Staining Methods—Histo-Chemical Tests—Methods for Special Organs—Histo-Pathological Processes—Bacteriological Methods—

Methods for Spirochaetes—Methods for Protozoa and Parasite Worms—are amply covered.

At a glance one believes, and upon study is without a doubt convinced that Mr Carleton has written a book of help and interest to all who are engaged in pursuit of the subjects presented.

MARGARET PADINE

**LIFE INSURANCE MEDICINE.** A Study of Some of Its Problems and Their Relation to Clinical Medicine. By Members of the Medical Department of the New England Mutual Life Insurance Company. Volume 1. Octavo of 219 pages with illustrations. Boston, New England Mutual Life Insurance Co., 1926.

The volume is a splendid contribution to Life Insurance Medicine as well as to clinical medicine. The section on Glycosuria and its significance is illuminating especially with reference to a differentiation and methods of approach in selecting a non-diabetic and an established pathological diabetic. The historic and early work with glycosuria has been thoroughly considered.

That section of the book devoted to "The Cardio-Respiratory Test" is most interesting and instructive. The author, Dr Howard M Frost, has made a real contribution to cardiology in placing before the medical profession this functional-circulatory test. Dr Frost states, "The need for a more adaptable test of Cardio-Vascular function has been apparent for many years. Reasoning from the previous observation that a considerable change in systolic pressure resulted from blowing steadily against resistance, the idea arose that by varying the intra-thoracic pressure one might produce a strain upon the cardio-vascular system with synchronous changes in blood pressure, cardiac rate or rhythm which would offer some indication of the severity of the strain and of the efficiency with which it was resisted."

The description of apparatus is given in detail as well as the technique for carrying out the test. Reactions to the test, both normal and abnormal are well described graphically with many case reports. The functional capacity and reserve of the myocardium is readily determined and a normal reaction curve established as a result of application and wide experience with this apparatus in competent hands. The actual presence of valvular disease is shown in many instances to be of little or in some cases no impairment at all in selection of individuals for standard life insurance. Numerous individuals studied previously and considered impaired lives after medical examinations have been found to show a normal reaction to strain put upon them by this functional test and have been accepted at standard rates for life insurance with an experience which now shows the practical value of this method in a study of 1500 cases.

G HOLBROOK BARRETT

**THE REPRODUCTION OF LIFE.** A Handbook of the Science of Reproduction in Nature and Man. By A J COCKINIS, F.R.C.S. 12mo of 287 pages illustrated. New York, William Wood and Company, 1926. Cloth \$3.50.

Book publishing houses are producing a considerable number of books on this subject. Some of them have a little virtue others much but this one falls in the former class as the author takes things for granted that are the subject of much debate. Often these matters are entirely open for investigation. He believes in acquired characteristics in a broadness that no one accepts and the theory of evolution becomes the law of evolution with him. Many well known facts are presented but there is too much taken for granted for this book to have an important place among the books on the subject.

J ARTHUR BUCHANAN

# BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits or in the interests of our readers.

- THE TIRED CHILD** By MAX SEHAM, M.D., and GRETE SEHAM, Ph.D. With a foreword by ISAAC A. ABT, M.D. 12mo of 342 pages, illustrated Philadelphia and London, J. B. Lippincott Company, [c 1926] Cloth, \$2.00
- FOUR THOUSAND YEARS OF PHARMACY** An Outline History of Pharmacy and the Allied Sciences By CHARLES H. LAVALLE, Ph.M., Ph.D. Octavo of 665 pages, illustrated Philadelphia and London, J. B. Lippincott Company, [1927] Cloth, \$5.00
- INTERNATIONAL CLINICS** Edited by HENRY W. CATTELL, A.M., M.D. Thirty-seventh Series, Volume 1 Octavo of 304 pages, illustrated Philadelphia and London, J. B. Lippincott Company, 1927
- LESSONS ON MASSAGE** By MARGARET D. PALMER. Revised and the Massage Section Rewritten by DOROTHY WOOD, M.R.C.S., L.R.C.P. Sixth Edition Octavo of 320 pages, illustrated New York, William Wood and Company, 1927 Cloth, \$4.00
- OUTLINES OF COMMON SKIN DISEASES INCLUDING ERECTIVE FEVERS** By T. CASPAR GILCHRIST, M.D. Octavo of 54 pages, illustrated Baltimore, The Williams and Wilkins Company, 1927 Cloth, \$1.50
- MOTHER AND UNBORN CHILD** A Little Book of Information and Advice for the Prospective Mother By SAMUEL RAYNOR MEAKER Octavo of 209 pages, illustrated Baltimore, The Williams and Wilkins Company, 1927 Cloth, \$2.50
- IMMUNITY IN SYPHILIS** By ALAN M. CHESNEY Octavo of 85 pages Baltimore, The Williams and Wilkins Company, 1927 Cloth, \$2.50 (Medicine Monographs Volume XII)
- CLINICAL NEUROLOGY FOR PRACTITIONERS OF MEDICINE AND MEDICAL STUDENTS** Largely Based Upon the Book by PROF. DR. HANS CURSCHMANN (A Free Translation with Changes and Additions) By EDWARD A. STRECKER, M.D., and MILTON K. MEYERS, M.D. Octavo of 410 pages Philadelphia, P. Blakiston's Son and Company, [1927] Cloth, \$3.50
- THE SPECIALTIES IN GENERAL PRACTICE** Compiled by FRANCIS W. PALFREY, M.D. Octavo of 748 pages Philadelphia and London, W. B. Saunders Company, 1927 Cloth, \$6.50
- A MANUAL OF PHARMACOLOGY AND ITS APPLICATIONS TO THERAPEUTICS AND TOXICOLOGY** By TORALD SOLLMANN, M.D. Third Edition, entirely reset Octavo of 1184 pages Philadelphia and London, W. B. Saunders Company, [1926] Cloth, \$7.50
- HEALTH SUPERVISION AND MEDICAL INSPECTION OF SCHOOLS** By THOMAS D. WOOD, A.M., M.D. and HUGH GRANT ROWELL, A.B., M.D. Octavo of 637 pages, with 243 illustrations Philadelphia and London, W. B. Saunders Company, 1927 Cloth, \$7.50
- APPLIED PHYSIOLOGY** By SAMSON WRIGHT, M.D. With introduction by SWALE VINCENT, M.D. Octavo of 418 pages, illustrated London and New York, Oxford University Press, [1926] Cloth, \$4.50 (Oxford Medical Publications)
- THE TREATMENT OF CHRONIC ARTHRITIS AND RHEUMATISM** By H. WARREN CROWE, D.M., B.Ch. Octavo of 196 pages, illustrated London and New York, Oxford University Press, [1926] Cloth, \$2.75 (Oxford Medical Publications)
- INDEX AND HANDBOOK OF X-RAY THERAPY** By DR. ROBERT LINK With a foreword by PROF. HOLZNER. Translated by T. I. CANDY, M.B., B.Ch. 12mo of 121 pages London and New York, Oxford University Press, [1926] Cloth, \$2.25 (Oxford Medical Publications)
- THE PSYCHO-PATHOLOGY OF TUBERCULOSIS** By D. G. MACLEOD MUNRO, M.D. 12mo of 92 pages London and New York, Oxford University Press, [1926] Cloth, \$1.75 (Oxford Medical Publications)
- HELIO-THERAPY** With Special Consideration of Surgical Tuberculosis By A. ROILLIER, M.D. [Second Edition] Translated by G. DE SWIETOCZOWSKI, M.D. Octavo of 318 pages, illustrated London and New York, Oxford University Press, [1927] Cloth, \$6.25 (Oxford Medical Publications)
- ELEMENTS OF HYGIENE AND PUBLIC HEALTH** An Introduction to Preventive Medicine for Students and Practitioners of Medicine By CHARLES PORTER, M.D. Second Edition 12mo of 425 pages, with 98 illustrations London and New York, Oxford University Press, [1926] Cloth, \$4.50 (Oxford Medical Publications)
- DISEASES OF THE INTESTINES** By A. P. CAWADIAS, O.B.E., M.D. Octavo of 299 pages, illustrated New York, William Wood and Company, 1927 Cloth, \$6.00
- APPLIED REFRACTION** By HOMER ERASTUS SMITH, M.D. Octavo of 131 pages, illustrated New York, William Wood and Company, 1927 Cloth, \$2.75
- X-RAY DIAGNOSIS** A Manual for Surgeons, Practitioners and Students By J. MACNUS REDDING, F.R.C.S. Octavo of 228 pages, with 80 Skiagraphic plates New York, William Wood and Company, 1927 Cloth, \$7.00
- MINERAL WATERS OF THE UNITED STATES AND AMERICAN SPAS** By WILLIAM EDWARD FITCH, M.D. Octavo of 799 pages, illustrated Philadelphia and New York, Lea and Febiger, 1927 Cloth, \$3.50
- MODERN MEDICINE** Its Theory and Practice in Original Contributions by American and Foreign Authors Edited by SIR WILLIAM OSLER, Bart., M.D. Third Edition, thoroughly revised Re-edited by THOMAS McCRAE, M.D. Assisted by ELMER H. FUNK, M.D. Volume 4 Diseases of the Respiratory System—Diseases of the Circulatory System Octavo of 1011 pages, illustrated Philadelphia, Lee and Febiger, 1927 Cloth, \$9.00
- THE MODERN PRACTICE OF PEDIATRICS** By WILLIAM PALMER LUCAS, M.D. Octavo of 962 pages, illustrated New York, The Macmillan Company, 1927 Cloth, \$8.50
- NOUVEAU TRAITE DE MEDECINE** Publié sous la direction de G.-H. ROGER, F. WIDAL and P.-J. TEISSIER. Fascicule IX Affections du sang et des organes hématopoiétiques Octavo of 802 pages, illustrated Paris, Masson et Cie, 1927 Cloth, 80 Francs

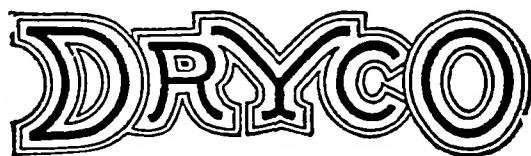

# In the Broadest Sense . . . . .

*"Nutritional disturbances are due to a disproportion between the nature of the food and the ability of the organism to digest and assimilate"*  
—Abt's "Pediatrics"

Restlessness, vomiting, loss of weight, are all manifestations of subnormal development and Pediatricists generally agree that almost every abnormal phase of infant life is closely linked to the subject of nutrition.

Clinical observation of infants and children over a period of many years conclusively proves that by virtue of the flocculent condition of the curd, DRYCO presents an optimum mixture for the physiological processes of digestion and consequently more easily satisfies nutritional requirements.

The later nutritional defects so frequently evident in the artificially fed, rarely manifest themselves in those infants fed exclusively with

## BEZOAR STONES

The May issue of the *Illinois Medical Journal* contains a notice of a book on Borneo Jungles by Dr William O Krohn, of Chicago. The following quotation is Dr Krohn's description of trade in bezoar stones

"There is one species of commercial transaction in which the Dyak has the edge on the Chinese trader. Usually the Chinaman takes advantage of the superstition of the humble Dyak, but here is one instance in which the tables are turned and the Dyak has full opportunity to take the Chinaman into camp because of the latter's superstitious belief in the magical medicinal properties of bezoar stones. The Chinese have their emissaries gather these stones' from all over the world. Bezoar stones belong to the 'aristocracy' of a Chinese doctor's heterogeneous collection of remedies. Medicinally a bezoar stone is an 'ultra' to the Chinaman as birds'-nest soup is gastronomically

"Speaking generally, bezoar stones are concretions sometimes found in the stomach or intestines of ruminants and some other animals and consist of mineral salts such as lime and magnesium formed about a nucleus of some foreign substance. Some contain hair or vegetable fiber. They are divided into three groups: the oriental from the wild goat of Persia and various antelopes, the occidental from the llamas of Peru, and the German from the chamois. Of these three the oriental is regarded as having the highest medicinal value, but in no wise comparable to that at-

tributed to those found in Borneo. Bezoar stones secured in Borneo are of two kinds

"1 Those that are simply gallstones of a monkey. These are greenish brown in color and are accredited with the greatest medicinal virtues by the Chinese

"2 Concretions that gather in an external wound of the porcupine. These, like the gall stones of the monkey, are of very light weight. They are of a brown color and taste like quinine

"When a Dyak has a bezoar to dispose of, he assumes a kingly attitude like unto that of an exclusive dealer in diamonds or pearls. He allows it to be noised about that he has one or more such priceless jewels' in his possession and leaves it to his fellow Dyaks to convey this information to the first Chinese trader that visits the kampong. It is beneath his new dignity to approach the Chinaman. The Chinaman must come to him, as he sits in his kingly state before his apartment of the tribal lamin. In the transaction that is sure to follow the Dyak does not, like the Chinese or other orientals, haggle and dicker, but sets his one price, which he will not reduce in the slightest, regardless of all discussion and argument. The Chinaman simply must come to his terms. It is gratifying thus to see the Dyak, in selling bezoar stones, score one on that slant-eyed trader. But eventually the Chinaman gets even, when, with a stock of tinselled ornaments and other baubles, he revisits the Dyak settlement just before a celebration of the Feast of the New Year"

## THE PHYSICIAN AND PREVENTIVE MEDICINE

The *Texas State Journal of Medicine* for May contains an editorial entitled "The Physician and Preventive Medicine" from which the following extracts are taken—EDITOR'S NOTE

"Until recent years the only preventive medicine practiced was by way of a side line with the physician engaged in the practice of medicine. There was no such thing as 'public health'. Indeed, health was a matter of most private concern to most people, and the subject was not one for discussion in polite society. The family physician had not then become extinct. That is to say, the physician had not abandoned or been caused to abandon, his complete responsibility for the physi-

cal, mental and even at times moral welfare of the families who committed themselves to his care. It is true that he did not collect for any service, as a rule, except that rendered the family in time of distress—and frequently not then. Nobody else knew anything about the art of medicine, and certainly nothing about the application of the science of medicine. The doctor had to be the authority on all such matters. Be it said to his credit, incidentally, he discharged this unpaid obligation 100 per cent and better, considering the state of his knowledge and the opportunity that he had to do so

(Continued on page 632, *adv* 211)

## THE COUNTY DISTRICT AND STATE MEDICAL ASSOCIATIONS

The *Journal of the Medical Association of Georgia* for May contains an article on the State Medical Society and its component societies by Dr C L Ayers of Toccoa, Georgia. The article might equally well be applied to New York State and illustrates the fact that physicians and their organizations are the same throughout the nations, as the following abstracts will show —

### EDITOR'S NOTE

"The County Society is an absolutely essential unit of medical organization. Our state and national associations cannot succeed unless the county societies properly function. It is in the county societies where the eligibility of physicians is passed upon, and when a member is admitted into the county society he automatically becomes a member of the state association and is eligible for membership in the A M A.

"In many of the Georgia counties there are only a small number of physicians, but our state parliamentarian has ruled, that two members can organize a county society, one for President and one for Secretary. So every county in Georgia should organize, in order that it may be represented in the State Association.

"Although the number of physicians in many counties is so small that it is not practical to have at their meetings a scientific program yet there are many things that can be accomplished by having regular meetings. In all matters pertaining to the public health, the opinions of the physicians in the community are sought, so they should get together and have a full and frank interchange of views, that they may have intelligent unity and harmony on all matters pertaining to health conditions. For instance, if there is an epidemic of any kind in the county and one doctor advises one method of dealing with it and another doctor some other method, then the lay, or county officials are at sea as to what procedure to take. Likewise, in order to secure helpful legislation, the profession should be in harmony, and should advise without legislative bodies, and by so doing could secure such laws as would protect the health of the community and safeguard many lives.

"Also occasional meetings of the doctors in a county promotes mutual respect and goodwill and goes far to destroy petty jealousies which often exist among fellow practitioners.

"I have felt for a number of years that the District Society is rendering more service to a larger number of physicians of the state than any other medical society.

"With our good roads and automobiles the district meeting is usually accessible to all the doctors in the district. The meetings being held

## Children Really Like This Pleasant Tasting Cod Liver Oil

When the physician prescribes cod liver oil, the administration of the oil is not always easy.

This is not a problem, however, when PATCH'S FLAVORED COD LIVER OIL is prescribed. Children (and older folks, too) really like it.

We had the patient in mind when we conceived the idea of adding a slight amount of flavoring to our vitamin-tested cod liver oil. This won immediate favor because it solved a real problem.

Owing to its high vitamin potency, the dose is small—one-half teaspoonful for children or one teaspoonful for adults. To guarantee the high vitamin potency, every lot of oil produced in our plants is biologically assayed in our laboratory.

The pleasant taste and the small dose make PATCH'S FLAVORED COD LIVER OIL a most desirable product.

If you wish to become better acquainted with this different kind of cod liver oil mail the coupon below for a sample and interesting literature.

(Continued from page 630)

"No matter what we do or how we do it, our purpose is to keep people from getting sick and to so improve their surroundings that when they do get sick they will be in a better position from a curative standpoint than they would otherwise be. In other words we get right back to the bedside, and no human being can comprehend public health or any other sort of medicine who has not thoroughly grounded himself in the fundamental principles involved in its practice.

"This is not to argue that every public health worker should be a doctor, nor that every doctor should be a public health worker. There is always a dividing line between the responsibilities that should be assumed by the lay health worker and those which should be directed by the trained and educated physician. Our success in the public health field depends absolutely upon our ability to determine in each instance just where this line lies. Because of the frailties of human nature, there will always be those laymen who resent the preeminence of the physician in the field, and who will strive to substitute for his services those of untrained, medically speaking, individuals who may be designated as 'sanitarians,' 'public health nurses,' 'sanitary engineers,' or what not. On the other hand, there will always be physicians who resent the intrusion of the layman in this field and will arise in the dignity of their profession and damn them all. The answer to the situation lies between these, and it is one of the hopeful signs of the times that the layman and the physician are combining their efforts rather judiciously on the whole, if uncertainly in many particulars.

"Unquestionably, the director of public health activities, speaking broadly, should have a medical education in advance of entering this special field. It is just as necessary that this be the case as it is that the man who specializes in eye, ear, nose and throat work, or surgery, or any other subdivision of the field of curative medicine, shall have had training in general medicine.

"The physician should not only maintain his position as the proper and legitimate repository of medical knowledge, in whatsoever field, but assume his share of the responsibilities involved.

"The hope of the lay public in regard to its physical condition is that these matters shall always be considered as strictly personal and to be handled on a private arrangement basis. Officialdom and bureaucracy cannot possibly have a place in curative, and it should not have a controlling place in preventive medicine."

## QUARANTINE METHODS

The *Nebraska State Medical Journal* for April prints a circular letter issued by the State Bureau of Health explaining the method of reporting and quarantining cases of communicable disease. New York physicians will be interested in the method because it is radically different from their own—*EDITOR'S NOTE*

"Note that the physician is only required to report his reportable cases to the secretary of the board having jurisdiction. In the county that is the county superintendent. In the cities, the secretary is the chief of police, and in the smaller towns, the city marshal. When the physician has so reported, he has done all that the law or rules require. It is no part of the physician's duty to establish and maintain quarantine, that being the duty of the police power of the state. In the county the quarantine officer is the sheriff, and it is his duty to establish and maintain quarantine or placard. The sheriff may delegate this to the attending physician if the physician sees fit to serve, but the physician is not required to act if he does not so desire. In the corporate limits of cities and towns, the physician must report to the chief of police or marshal. When he has done so, he has complied with all the law and regulations required, it being then the duty of the chief of police or marshal to establish and maintain quarantine.

"When the minimum time of quarantine is up, and the attending physician is satisfied that the case is safe to release, he should so notify the quarantine officer. Then it is up to the Board to see to the release. But if such Board does not deem it best to issue a release, the attending physician need not worry or bother himself further in the case, as he has discharged his full duty to his patient, and the responsibility for release rests with the Board.

"Uniformity and system in the matter of handling contagious diseases will make for efficiency the same as in any other activities."

### AMBROSE PARÉ

The May issue of the *Virginia Medical Monthly* has the following observations on Ambrose Paré the famous French surgeon, and father of surgery.

"Paré was a very practical man, full of common sense, and was more impressed by results than he was by the opinions of authorities. In 'The Apology and Treatise' in which he replies to Gourmeien's condemnation of his use of ligatures in amputations, while he cites authorities to show that bleeding vessels should be tied, he relies chiefly on re-citing successful cases to prove the correctness of his operation. His zeal in the quest for successful remedies is shown in the puppy fat

# MAMMALA

## The Only Scientifically Modified Milk for Babies and Invalids

MAMMALA is pure fresh cow's milk of the best quality, modified for Babies, Children and People of All Ages by removing a part of its cream and by adding a suitable proportion of milk-sugar, and then dried rapidly by the scientific process of HATMAKER, which kills all disease germs that may be present and makes it safe and preservable. It is composed entirely of milk constituents and does not contain any starch, malt, cane-sugar, bicarbonate of soda or other foreign substance. It is a very nutritious balanced complete food which is easily digested and very completely assimilated.

twice in each year gives every physician an opportunity to present a paper, if he desires, and many more should avail themselves of this privilege than do. Some of the very best scientific programs I have ever attended have been at district meetings.

"Membership in the State Association carries with it many advantages. The scientific programs are always good and if well attended is equivalent to a short post-graduate course. The social entertainment is usually splendid, and more so now since the ladies' auxiliary has added so much to this feature. Membership in the State Association gives each member a splendid monthly Journal, which ranks among the best state journals in the United States. Membership entitles each member to the medical defense feature, if he happens to need it. The scientific and commercial exhibits are usually good and instructive.

"One of the greatest fields of service of the State Association is in the line of public health work, to enlighten the general public on health problems, and by helping to secure such legislation as will aid in preventing diseases, and thereby prolonging and adding comfort to life. In contrast to the indifference of former days, popular interest in preventive medicine is now widespread and rapidly growing.

"Membership in, and active participation in the work of a medical society, are of great educational value to the physician. It affords personal contact with fellow practitioners in the courteous discussion of medical subjects and professional problems and promotes mutual respect and goodwill.

"Concise written reports of interesting clinical observations presented before medical societies, and for publication, are splendid means of self-education and furnish a valuable addition to medical literature.

"The desire for recognition and honor is natural, but all cannot be Presidents of the A. M. A., the Southern, or the State Association, but every reputable physician can be a member of his county, district, and state societies, and by so doing, better equip himself to serve those who employ him. After all, far more important than honor or recognition is the laudable desire which finds satisfaction in work well done, whether any one sees it is well done or not.

"If we would get the most out of our professional lives, we should be constantly endeavoring to add to our knowledge and equipment as physicians. I know of no better way than the systematic reading of medical journals, an occasional post-graduate course, and the attending of medical meetings both County, District, and State."

## THE WOMAN'S AUXILIARY OF THE MEDICAL SOCIETY OF NEW JERSEY

The progress of the Woman's Auxiliary of New Jersey will interest the doctors of New York State in view of the approval of the auxiliaries by the House of Delegates of the Medical Society of the State of New York.

The Journal of the Medical Society of New Jersey for May describes the formal organization meeting of the State Auxiliary which will be held on June 9, during the annual meeting of the Medical Society of New Jersey at Atlantic City. The program reads:

"Launching of the Women's Auxiliary to the Medical Society of New Jersey will take place at a meeting in room 'H' of the Hotel Haddon Hall, Atlantic City, Thursday, June 9, 1927, at 3 P. M. Dr. James S. Green, President of the Medical Society of New Jersey, will open the meeting and introduce Mrs. W. Wayne Babcock, of Philadelphia, Chairman of the Organization Committee of the Woman's Auxiliary to the American Medical Association, who will address the assemblage on 'The Reasons for Forming Auxiliaries to Medical Societies'.

"This address will be followed by a short talk on 'The Opportunities Knocking at the Doors of State and County Auxiliaries,' by Dr. J. Bennett Morrison, Recording Secretary of the Medical Society of New Jersey.

"The meeting will then be turned over to Mrs. Samuel Barbash, Chairman of the Organization Committee, who will report upon the work accomplished in organizing county branches, will present the list of delegates chosen by the county auxiliaries to attend this convention and will introduce Mrs. A. Haines Lippincott, as the first President of the Woman's Auxiliary to the Medical Society of New Jersey, with authority to proceed with formal organization of such a body. Following

presentation of the other temporary officers appointed by President Green as previously mentioned, organization will proceed under the presidency of Mrs. Lippincott.

The same issue contains the following news of the State Society auxiliaries:

"As recorded in the March and April numbers of the Journal, plans for the organization of a Woman's Auxiliary to the Medical Society of New Jersey are developing rapidly and satisfactorily. At the present moment thirteen counties have organized and five others have engaged to consider the matter during the month of May, the remaining three may come into line before the June session of the State Society, at which time an amalgamation of the county branches into a state auxiliary is scheduled to take place.

In view of the fact that the American Medical Association will be meeting at Washington in May, and the Woman's Auxiliary to the National Association will hold its annual convention at the same place and time, and because we desire to have New Jersey represented at the convention it became necessary to make special arrangements for selection of delegates from the state. Accordingly, anticipating the actual formation of a state auxiliary when county delegates shall gather in convention in June, the President of the Medical Society of New Jersey, Dr. James S. Green at the request of the Organization Committee, decreed the formation of a skeletal organization and appointed the following temporary officers to serve until the state auxiliary shall have become formally organized, President, Mrs. A. Haines Lippincott, of Camden, First Vice-President Mrs. Walt Conway, Atlantic City, Second Vice-President, Mrs. E. R. Mulford Burlington, Recording Secretary, Mrs. A. L. Stillwell, Somerville, and Treasurer, Mrs. James Hunter, Jr., Westville.

(Continued from page 635)

episode At Turin he met a surgeon who claimed to have an invaluable remedy for arquebus wounds, and it was two years before he could get from him the secret recipe, which consisted of new-born puppies boiled in oil of lilies, mixed with earthworms, prepared with oil of Venice Arabian ideas in therapeutics were still dominant throughout Europe Bezoar stones were thought to be universal antidotes Charles IX had such a concretion of which he was very proud, and Pare persuaded the king to try it on a criminal who was condemned to death Accordingly the criminal was given a poison and immediately the bezoar stone, but died in seven hours At the autopsy, Paré showed that he died of corrosive sublimate poisoning His opinion of mummy and unicorn's horn two remedies held in the highest esteem, is interesting Both were costly remedies and as the result, mummies were sometimes made in France Pare says, 'Nevertheless, I believe that they are as good as those brought from

Egypt, because they are none of them of any value Thereupon we will send them back to Egypt, as we will the unicorn to inaccessible deserts'

"Pare's practical nature is further shown by his clinical observations He was the first to suggest that syphilis was the cause of aneurysm When alopecia is due to this disease, the patient is to be rubbed with mercurial ointment 'until he enters the kingdom of Bavaria,' a pun on the French word baver, to salivate Pare was the first to discover at autopsy metastatic abscesses of the internal organs following wounds Finally as an evidence of Pare's common sense, is his experience during the massacre of St Bartholomew He pursued his calling with such singleness of purpose, and was withal so useful, that his religion was unnoticed Charles IX is said to have commanded Pare to come to the king's chamber and not to budge from it, saying that 'it was not right that one who could save so many poor people should be thus massacred'"

# DR. BRUSH'S Kumyss

Reg U S Pat. Off

When E. F. Brush, M.D. perfected his Kumyss fifty two years ago and offered it to the medical profession, it won their confidence immediately, which it has since retained. During that time no deviation has been made in its preparation, there has been nothing added to it or taken from it. The medical profession can therefore still repose the same confidence in Dr. Brush's Kumyss as they have from the time it was first made.

Dr. Brush is too advanced in years now to give his individual attention to the preparation of his Kumyss, he did, however, carefully train others and the preparation of his Kumyss is now under the personal supervision of one who received his training directly under Dr. Brush.

The foregoing may be reassuring to the medical profession at the present time.

Samples sent free, prepaid to destination on receipt of request.

## BRAUN'S SNARETOME

Tonsillectomy may be a minor surgery, but it requires its men to cope with it and the instrument to perform it.

It is only a few years since Dr. Braun's tonsillotome was given to the profession, but its merits are daily realized.

Combining the sluder and the snare method, it incorporates the advantages of both with none of the faults of either. Results gained practically no hemorrhage, no trauma, applicability of the instrument to every type of tonsil—simple and easy technique are essential enough not to be overlooked. Sold by F. B. Meyrowitz Surgical Instruments Co., New York, N. Y. See advertisement page 111—Adv.

## THE SPIRELLA FIGURE

The Spirella Figure Training and Supporting Garments embody peculiar features which belong to that particular brand exclusively.

They support the part and work in harmony with the muscles, joints and bones and permit full freedom of motion and normal pose, thereby promoting health and beauty of figure especially in women. See their advertisement page 11—Adv.

## THE FISHER METHOD OF COLON IRRIGATION

Irrigation as Employed in the Treatment of Chronic Intestinal Stasis by Recently Developed Technique

"We are fond of thinking how modern science is wiping out plagues and extending the field of preventive medicine. It is then with something of a shock when one reads that too many physicians look with coldness on modern discoveries. In consequence only a limited number of people are receiving the best that science can afford." (From an editorial in THE NEW YORK STATE MEDICAL JOURNAL.)

For proper irrigation we must bear in mind the wise comment of J. P. Thornley, M.D. (in the *Medical Times*, July, 1924) "Like everything else, this simple little operation may be well done or poorly done and, except by accident, it is not one that any fool can do well. This the patient will appreciate more than the surgeon."

The Apparatus as employed in the FISHER METHOD OF COLON IRRIGATION is fully described in our booklet, sent on request. See advertisement page 111—Adv.

## THE WOMAN'S AUXILIARY OF THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA

The Atlantic Medical Journal, the organ of the Medical Society of the State of Pennsylvania, contained news of the Women's Auxiliaries of five counties

### From Beaver County

After a delightful luncheon and the regular business, the meeting was continued with reports from the chairmen of committees

The Hygeia campaign is being carried on most successfully, with a total of eighty-three subscriptions reported. We hope a few more months of work will add substantially to this number

The chairman of Public Health reported the splendid success of the campaign for the immunization against diphtheria. Beaver County is among the foremost in the State in the percentage of immunizations which were carried out

Five new names added to our membership was the report from the Membership chairman, increasing our total enrollment to fifty-six

After a general discussion it was decided to hold a card party to reimburse our treasury. This was referred to the proper committees

The Reverend Doctor Bostick, speaker of the day, then gave a very interesting book review of Channing Pollock's "Enemies," after which the meeting adjourned

### From Greene County

After a short business meeting, Mrs S T Williams, chairman of the entertainment committee, presented a program of musical numbers—violin and piano—given by Misses Louise Scott and Bess Moredock. Interesting selections were read by several of the members Mrs

This unqualified guarantee goes with each and every carton of

Prepared Casein

## Dietetic Flour

More of this Flour is prescribed by New York State Physicians than anything else of its kind. The variety of foods that are so easily made in the patient's home are both palatable and attractive. Listers Flour is self-rising and a Recipe Booklet is in each carton

New York City

and  
**LISTERS, Limited**  
Huntingdon, P. Q., CANADA

W M Parry gave a report on auxiliary meetings which she had attended in the States of West Virginia and Tennessee. Refreshments were served and a social hour enjoyed

### From Montgomery County

Dr A C Morgan, president-elect of the State Society, gave a very instructive talk on the work we, the doctors' wives could do as Auxiliary members

Dr George A Knowles, chairman of the State Society Legislative Committee, also gave a short talk on legislative matters

When the Auxiliary was organized in 1924 it was decided to hold only three or four meetings a year, but the enthusiasm has so grown that we find holding the meetings every other month does not seem too often

At the close of the meetings, refreshments were served to the doctors

### From Philadelphia County

Dr Frederick S Baldi, President of the Philadelphia County Medical Society, addressed the meeting

The Chairmen of the various standing committees made their annual reports, after which officers were elected for ensuing year

During the past year the definite object of the Auxiliary was the purchase of and the payment for the beautiful Steinway piano which it presented to the Philadelphia County Medical Society. This has been fully accomplished, and the Auxiliary has also purchased some very attractive china and silver for its own use, and still there remains in the treasury a substantial sum of money

### From Westmoreland County

The Westmoreland County reported on its election of officers and a bridge tournament

## POLYCYSTIC KIDNEY WITH REPORT OF A CASE

By JOSEPH L TENENBAUM, M D

Attending Urologist, Central Neurological Hospital Welfare Island, New York.

**P**OLYCYSTIC kidney is a congenital deformity consisting of cyst formation in the cortex. The origin of this condition is still a disputed question. The most plausible explanation is offered in the theory of embryonic malformation (lack of union between the tubules and the metanephrogenic anlage). It is often hereditary. Cystic degeneration may be fully developed in the foetus and present an obstacle in normal delivery. In most of the cases that come to our observation, the anomaly is latent for many years and starts to develop after middle age. The kidney grows larger and may attain enormous sizes. The bulk of the kidney consists of multilocular cysts, separated by layers of connective tissue. The cysts vary in size and number. Their content is liquid, viscid, albuminous or bloody. The cysts develop at the expense of the kidney substance. The latter is compressed, its capillaries are occluded and the parenchyma undergoes atrophy and cicatrization. The condition is essentially bilateral. The cysts do not have any direct communication with the lumen of the pelvis. Similar cysts have been observed in the liver.

**Symptomatology.** The symptoms accompanying this disease are not pathognomonic. Many a diagnosis has been made by accident. The condition does not cause complaints unless the degeneration has progressed to a large degree. The symptoms can be divided into four groups.

**A**—The largest group of cases exhibits diagnostic features which are commonly observed in chronic interstitial nephritis. The similarity of those two conditions is based on anatomical grounds, such as atrophy and scarring. Polyuria, low specific gravity and inability to concentrate the urine accompany every case of polycystic kidney. Albuminuria, a few hyaline casts, microscopic blood and a few pus cells may be present. Circulatory changes, such as high blood pressure, hypertrophy and dilatation of the heart muscle are common occurrences. Bleeding from the nose, gums and

lungs, edema, hydrothorax and ascites may result from cardiac failure. The main complaints, however, which alarm the patient, are preuremic symptoms, such as headaches, nausea, lack of appetite, vomiting, lassitude and the like. They may persist for years. As destruction of the kidney substance progresses and the excreting ability of the kidneys diminishes, there will be retention of nitrogen bodies in association with other signs of renal impairment. The preuremic stage gradually develops into uremia.

**B**—Another set of symptoms is due to the growing size of the tumors. Backache, neuralgic pains in the loins with occasional renal colics, are often experienced. There are recurring symptoms of constipation and gastrointestinal disturbances which are partly due to direct pressure and partly to toxic absorption.

**C**—From those are to be differentiated the symptoms which are growing out of complications, such as infection, abscess of the kidney, stone formation, etc. Either of them may be of such nature as to obscure the original picture. Pyelitis is a very frequent complication in polycystic kidney. Deformation of the pelvis and dislocation of the calices favor urinal stasis and infection.

**D**—Hematuria is a frequent occurrence in polycystic kidneys. The amount of blood may vary from a few blood corpuscles in the urine to profuse hemorrhages. They contribute to the anemic condition of the patient. They are due to the same factors that are encountered in chronic nephritis. More alarming are profuse hematurias, some of which are caused by rupture of the cysts. The bleeding may be uncontrollable. A certain diagnostic feature of the hematurias in polycystic kidneys is the passage of masses of old blood, coffee-like, or even tarry in color. They are due mostly to bleeding occurring in the isolated sacs which subsequently rupture into the pelvis.

**Diagnosis.** The diagnosis of polycystic kidneys may offer several difficulties. In the early stages, recognition is almost impossible. The

## WHY DRY MILK

The production of clean milk is engaging the attention of health authorities to a greater extent than ever before. The heavy toll in lives which liquid milk has taken in the past and is still taking, notwithstanding many regulations and inspections by Health Departments, has called for efforts on the part of all milk producers to reduce this milk hazard.

In 1893 pasteurization was first attempted. Pasteurization has done much to eliminate milk-borne infections. However, in order to be safe, milk must be carefully pasteurized and health authorities everywhere are taking steps to see that the pasteurization is carefully carried out. This, of course, involves the human equation and there are records of many epidemics caused by milk supposed to have been pasteurized in which Pasteurization has been faulty.

One of the greatest steps taken in safeguarding the milk supply was the production of dry milk. Dry milk has been produced on a commercial scale since 1903. The product, for many years, was poorly made and was used largely by bakers and confectioners. With the appearance of Dryco, a special dry milk of high quality, absolute safeguarding of the milk supply was assured. Not alone is Dryco a clean and safe milk, but it is a highly digestible milk very effective in the feeding of infants, especially in difficult feeding cases. Physicians have been prescribing it for many years, relying not alone on its safety, but on its excellent nutritive qualities as well.

The latest step in improving the nutritive qualities of Dryco has been taken recently—the irradiation of Dryco by the ultra violet ray. Adv

## COLOSTOMY APPLIANCES

Within the last 10 years, the technique of colonic operations has been so wonderfully developed that thousands of patients have been saved. In order to assist those patients after the operation has been successfully performed, it was necessary to devise a Colostomy Pouch, which the patient can wear with comfort, in order to keep his body perfectly clean and also supply him with an appliance which can be kept sterile.

THE WILLIAM M EISEN COMPANY, after several years of experimental work, finally succeeded in perfecting a Colostomy Pouch, which has all the qualities and advantages required for that purpose.

THE EISEN COLOSTOMY POUCH is made with a pneumatic soft rubber cushion, inter-changeable receptacles, a very light non-rustable metal cup, and an elastic adjustable body belt which is detachable from the Colostomy Pouch. The cup and pouch which lies over the artificial rectum can be easily cleaned, and there is no possibility of any leakage between the pouch and the opening of the artificial rectum, when applied to the body.

This pouch is recommended by a great many leading Surgeons all over the country, and recognized as a most satisfactory appliance. See advertisement on page xiv.

## MAMMALA CORPORATION

We are pleased to have Mammala return to our advertising columns. It was the original dry milk for Babies and Invalids and it has given the users great satisfaction for over twenty years—See advertisement, page xiv.

COLOSTOMY POUCHES  
No. 3000

This apparatus for artificial Anus is the most sanitary and practical of its kind. The body plate and drain funnel are of white metal and a pneumatic ring between body of patient and plate serves to make the latter cling close to the body. Two rubber pouches of the necessary size are supplied in order that one may be thoroughly cleansed and deodorized while the other is in use.

RECEPTACLE FOR NATURAL ANUS

With Body Belt  
The only appliance made for the non-retention of stool. Will take care of the natural discharge in a clean and efficient manner. Made entirely of soft rubber assuring comfort to patients.

SUPRA PUBIC DRAINAGE APPLIANCE  
An apparatus devised for the purpose of receiving the Urine while drainage is taking place after a bladder operation.

urinary complaint. The patient had no venereal disease. He passed a healthy childhood and adolescence. He consumed no alcohol and was a moderate smoker. Fifteen years ago, the patient had renal colics for eight days, following which he passed two small stones in the

*Physical Examination* The patient is well built and well nourished, with a sallow, yellowish tinge of the skin and anemic mucous membranes. His lungs were negative. His heart was found markedly enlarged to the left. The heart sounds were clear with the second aortic accentuated. His blood pressure was 180 systolic and 105 diastolic. The abdomen was distended. In the left and right hypochondrium, two tumors were palpated, reaching down to the umbilicus. The tumors were elastic, hard, with no sign of fluctuation. The right mass seemed somewhat larger than the left. Examination per rectum proved negative.

A Pyelogram Right Polycystic Kidney

B Pyelogram Left Polycystic Kidney

urine. Since then, he had nothing to complain of, except that he was told that he has high blood pressure, which went up at one time to 250 systolic. Two months previous to the examination, the patient passed brown, coffee-like urine. After two weeks, the urine cleared up. He had repeated bleeding from the nose and itching of the skin. His present symptoms started a week ago with headaches, dizziness, lack of appetite and constipation, which was not relieved by enemas. He had frequent vomiting spells. He had fullness in the abdomen and was advised to see a gastro-enterologist. He had no blood in the urine lately and no urinary complaints, except some frequency during the last few nights, which he attributed to drinking of much water.

Urological examination revealed a small meatus of the urethra. On cystoscopy, the bladder was found normal. Both ureteral orifices were located and a catheter inserted into each ureter. Both kidneys were draining at a frequent and irregular rate. On aspiration, several small syringes of pelvic residual were obtained. The specimens contained a large number of pus cells. The culture proved negative for organisms. A functional test performed with indigo-carmin injected intravenously gave a faint greenish-blue return from the left kidney in 20 minutes and none from the right side up to 25 minutes. Two pyelograms were taken at different intervals.

maladies most frequently mistaken for polycystic kidneys are hydronephrosis, neoplasm echinococcus, perinephritic hematoma, solitary cyst, etc. Bilateral localization is quite pathognomonic for polycystic kidneys. However, double-sided hydronephrosis, a neoplasm involving both kidneys or echinococcus may simulate polycystic kidneys. Palpation will often help to differentiate those conditions. A well developed polycystic kidney presents a large, elongated tumor with a hard, irregular, nodular surface moving on respiration. No fluctuation can be elicited.

Urological examination, consisting in catheterization of the ureters, functional tests and, especially, pyelography, is of great aid in arriving at a concrete diagnosis.

Catheterization will often reveal retention in one or both pelves, containing pale urine of low specific gravity. The amount of the residual varies. The discharge of urine is irregular and arrhythmic (Ludovig). On retiring the catheter, one often discovers new areas not drained previously.

The functional test has a certain value as a comparative index of the function of each kidney, but more so as a test showing delayed secretion from either kidney. At times, the dye does not make its appearance up to 20 and 25 minutes in one or both sides.

Pyelography gives the most interesting results. Owing to the size of the kidney, the pelvis and the calices are stretched out in their longitudinal aspect. Accordingly, the middle calyx is shortened or almost obliterated (dragon form). The upper and lower calices likewise vary in size and shape. Some present long, tapered projections (spider form), others are dilated with flattened-out or clubbed edges. Some of the calices may be compressed by cysts tending toward the pelvis with partial encroachment and filling defects simulating hypernephroma. However, the appearance of the pyelogram as a whole rarely fails to identify the condition.

**Prognosis** Polycystic kidney is an incurable disease. The span of life from the time the diagnosis is made varies in each individual case, according to the progress of the disease. The statistics offer from one to twenty years of life. Blood chemistry and functional tests are barometers indicating the gathering of the storm. There are frequent remissions and exacerbations of symptoms. Intercurrent diseases, infections, excessive hematurias and cardiovascular failure, may accelerate the nearing end.

**Therapy** The treatment is essentially symptomatic. The regime prescribed for the patient does not differ from that in chronic nephritis. It is to be borne in mind that the patient is a cardiac as well as a "nephritic" and that from

the inter-relation of the circulatory and secretory systems depends his life and comfort. Accordingly, our medication will have to conform to both conditions. Thus, while limitation of purins, salt and spices is an accepted dietary rule, at the same time, one must be guarded against overstepping certain limits. The possibility of protein starvation and weakening of the heart muscle is one of the drawbacks of too restricted a regime. Forced fluids, while necessary for dilution of toxic substances and encouraging kidney secretion, have their limitations in cases of excessive hypertonia. The gastrointestinal tract, which bears the brunt of elimination, should not be neglected. Elimination through the skin should be encouraged. Another important point to remember is the fact, that while the diminished reserve power of the kidneys may suffice under ordinary circumstances, its insufficiency and unstable equilibrium may manifest themselves as soon as living conditions are being suddenly or gradually disturbed. The general condition of the patient, his ability to go about his work or to undergo any undue strain, should be tested in each individual case. In other words, the old truism to treat the patient, not only the disease, has its full significance in cases of polycystic kidneys.

As poor as the results of medical treatment may be, surgery has much less to offer. The condition does not lend itself to radical surgery. Nevertheless, one may be prompted to proceed with a nephrectomy on account of certain dangerous complications like pyonephrosis, tuberculosis, uncontrollable hematuria and the like. The fate of the patient depends, of course, on the function of the other kidney. As the degenerative process in the other kidney is not halted by nephrectomy, the latter offers only symptomatic relief. The mortality is as high as 30 per cent. Decapsulation and nephropexy advocated by some authors are technically difficult and offer scant relief. Nephrotomy has been performed with the same prospects. The best that can be done for those cases which are in need of immediate relief is incision or resection of the cysts. The use of the cautery (ignipuncture) is the method of choice. However, as many of the cysts lie deep in the kidney substance and cannot be reached by the operator, this procedure while not as dangerous as the previously reported, is, nevertheless, far from being a radical cure. The following case is reported as an illustration.

**Report of the Case** Mr. I. F., 50 years of age, married, father of three healthy children, was referred by Dr. S. Nagel on November 2nd, 1926, for urological examination. His hereditary history is of no special interest. His brothers and sisters are living and none of them has any

of the general practitioner can be readily appreciated. He is usually the first one to be called on and he has to decide to what specialty it belongs and which specialist is correct in the diagnosis. This paper is intended to present to the general practitioner the recent findings and accepted methods in diagnosis, differentiation and general mode of treatment.

## 2 NORMAL PHYSIOLOGY OF THE SPINE WITH REFERENCE TO THE USE OF THE BODY IN PROPER POSTURE

Goldthwaite<sup>2</sup> and his school at Boston have done meritorious work on the normal spine. I need not go into detail but will merely mention that they have demonstrated the great influence which the proper posture of the spine has on general health. Goldthwaite<sup>2</sup> outlined the different types of the spines.

(1) The normal human type with its four curves (a) the cervical, with the convexity anteriorly, (b) the dorsal, convexity backward, (c) the lumbar, curved forward, and (d) sacral, convexity backward. But all these curves are only slight. The exaggeration of any of these curves causes trouble.

(2) The second type, which is abnormal, is the congenital visceroptotic—slender or carnivorous type.

(3) The broad backed or herbivorous

(4) The mixed human type

This classification is made use of in industries where many people are employed, a certain type of individual is selected for certain work.

The human spine is not an extremely flexible structure by itself. Motion takes place mainly at the cervical and lumbar regions. Motions permitted are flexion, hyperextension and side bending rotation. It must be remembered that the intervertebral discs by permitting compression give freedom to the motions. The discs atrophy with age hence the bowed back of old age. The joints of the spine are very many and complicated. There are 134 joints between the base of the occiput and the sacrum, demonstrating how even small injuries to the spinal column are apt to cause severe disability.

The Boston school has emphasized that habits of posture affect the physiology of the body, especially the digestive, respiratory and circulatory systems. (We breathe better when we stand erect. The typist makes less mistakes when she has a good chair. The seamstress or factory worker has no backache and turns out more work when the chair and the working table are properly arranged.) In preventive medicine the physical education in proper posture should play a very important role.

The rules and principles for acquiring and maintaining the proper mechanics of the body in

its anatomic correct position are few and should be summarized by every physician. Thomas and Goldthwaite<sup>3</sup> suggest these short orders: "Stand tall, head up, chin in, chest high, abdomen flat, weight on balls of feet. Never over-correct the chest which tends to carry the shoulders too far back and to increase the lumbar curve causing the body weight to fall on the heels."

Radiograms of the spine show that even in normal individuals there are many anomalies. There are extra vertebrae, ribs or abnormally large transverse processes (O'Reily<sup>4</sup>, Moore<sup>5</sup>). These abnormalities may never give trouble and are discovered only accidentally. Hence a diagnosis of a physical abnormality should not be made unless it can be otherwise proven to be responsible for the condition. Radiograph in antero-posterior and lateral views are essential in diagnosis.

## 3 CAUSES OF BACKACHE

The causes can generally be divided into five groups:

A Those due to arthritis of the spine.

B Those which are traumatic in origin.

C Those due to attitudinal or mechanical strain—static backache.

D Those due to neoplasms.

E Those due to uterine, pelvic and abdominal causes.

### A I ARTERITIS OF THE SPINE

Arthritis of the spine occurs as primary arthritis of the spine (Spondylitis Deformans) or in connection with general arthritis (Hypertrophic arthritis).

(a) The form called Spondylitis Deformans or Spondylose Rhizomelique or "Poker Spine" is a chronic and progressive disease of the spine which terminates in ankylosis and deformity. It may be localized at first but tends to spread until the whole spine is involved. It is an ossifying periostitis which binds the vertebrae together. The vertebral discs gradually disappear and osteophytic outgrowths appear along the margins of the bodies of the vertebrae.

*Clinical Feature of Spondylitis Deformans*—There is generally a history of an acute onset of pain and stiffness in the back sometimes radiating to the hips. Gradually the spine becomes stiffer and the figure more stooped.

*Treatment*—Remove the cause, if possible. Keep the spine in a good posture so that if ankylosis does occur, it should leave the patient with a good straight spine. In the acute stage, a corset and then a brace should be used. Later on hot packs, baking, heliotherapy and massage may be instituted. Patient must be instructed in the proper exercises for developing the spinal muscles.

(b) In cases of chronic polyarthritis the spine is usually free but with hypertrophic arthritis (osteo-arthritis) the spine is a part of the general

The right pyelogram shows the typical dragonform of the pelvis and calices stretching out between the brim of the pelvic bone up to the eleventh rib. The left pyelogram gives evidence of a shorter and wider pelvis and middle calyx, with better developed upper calices. A comparison between the two pyelograms suggests more kidney destruction in the right than in the left side.

A blood chemistry performed on November 14th, 1926, gave the following results: Urea—120 mg, Creatinine—4 mg, Sugar—73 mg, and Uric Acid—10 mg, per 100 c c of blood.

Under suitable medical treatment, proper diet and rest, the patient's condition has been gradually improving, so much so that he was able to return to his work (designing). Pelvic lavages with silver nitrate solutions ( $\frac{1}{2}$  per cent) have been instituted in order to clear up the pyelitic infection. The patient was lost track of later.

**Summary** Polycystic kidney is one of the

most interesting maladies. Not unlike the neoplasms, cystic degeneration while based on congenital malformation, makes its appearance either in the very young or after middle age. Its development cannot be traced back to any particular factor. It is a progressing disease and results in tumor-like formation. As far as the prognosis is concerned, it shares the fate of malignancy. It does not metastasize, however. It is primarily a degenerative process with secondary atrophy and connective tissue proliferation, while neoplasm is primarily a process of neoplastic proliferation with secondary degeneration. The treatment is essentially symptomatic.

### 1 INTRODUCTION

OF all the afflictions to which the patient is exposed, the one which most taxes the skill of the specialist is "backache." The gynecologist, genito-urinary surgeon, internal medical man and the neurologist consider its diagnosis and differentiation a considerable problem. The orthopedic surgeon, who sees most of the cases, is also often at a loss for the proper diagnosis and for the treatment that will best hasten recovery.

Backache from all causes is very frequent in civil practice. The "lame back" constitutes more than 20 per cent of all the industrial accident cases\*, according to the statistics of Osgood. Where litigation is pending, whether in industrial or other accidents or if the patient is a neurasthenic, the subjective symptoms of backache are likely to be markedly exaggerated. The symptom complex is obscure and will tax the skill and patience of the most experienced surgeon. The situation is further complicated by the fact that the osteopaths and the chiropractors make their strongest bid in promising sure and rapid cures of this malady.

With all these difficulties in mind, the dilemma

\* Read before the Bronx County Medical Society February 16, 1927

over the lower spine and hip radiating to one side down to the knee and leg. The pain is usually asymmetrical; sciatica is a frequent symptom. There is a great deal of pain in turning from side to side in bed. The spine often shows a deflection or tilt to one side.

For the orthopedic surgeon it is necessary to differentiate between the two but for the general practitioner it is sufficient to consider them as one.

Smith-Petersen<sup>7</sup> has ably given the differentiation between these lesions as follows:

This strapping is changed every five days for a few weeks then a brace is applied when barking and massage can be instituted.

### (c) ATTITUDINAL STRAIN—STATIC BACKACHE

—Jones and Lovett<sup>8</sup> introduced this term to define disturbances caused by the erroneous deflection of body weight causing strain to spinal muscles, joints and ligaments. The deviation may be (a) in the lateral direction or (b) in the anteroposterior direction.

## DIFFERENTIATION BETWEEN LUMBO-SACRAL AND SACRO-ILIAC

	<i>Lumbo-Sacral</i>	<i>Sacro-Iliac</i>
1 History	More comfortable on either side or back.	Cannot lie for any length of time on the side complained of.
2 Distribution of pain.	Projected or referred along the distribution of 5th lumbar and first sacral nerves, i.e., dorsum of foot, first toe, mesial aspect of the sole and heel and antero-lateral and posterior aspects of the lower leg, dorsum of the foot, 2nd, 3rd, 4th, and 5th toes and lateral aspect of the sole of the foot.	Pain referred along the fourth and fifth lumbar and first and second sacral nerves, i.e., posterior aspect of thigh as well as any part of the lower leg, usually antero-lateral and posterior aspect of the lower leg and lateral aspect of the ankle.
3 Examinations.		
A. Motions standing		
a. Flexion.	Lumbo sacral region rigid. Forward bending takes place at the hips and upper lumbar spine and dorsal regions.	Bends lumbar spine first then tilts the pelvis until the hamstrings become taut, then patient either stops or flexes his knee on the affected side.
b. Extension.	Lumbar spine kept rigid and bends knees.	Lumbar spine moves and pelvis tilts backward.
c. Lateral flexion or side bending	No motion in lumbo sacral junction—Only motion in the dorsal and upper lumbar spine. Freer on the side away from the affected.	(1) In acute inflammatory cases motion is more limited toward the side affected. (2) In sacro-iliac strain the reverse is true.
B. Motions sitting	Flexion is limited.	Flexion is free.
C. Motions lying	Pain present. The lumbar spine cannot be flexed.	Motion free except in severe cases.
a. Passive flexion (flexing knee and hip)		
4 Special tests.		
a. Straight leg raising of affected side. (One hand should be under the patient's lower spine.)	Pain does not come on till after the lumbar spine begins to move.	Pain brought on before the lumbar spine begins to move.
b. Straight leg raising of unaffected side.	Pain is at the same level when the other leg is raised.	It is possible to bring the opposite leg to a higher level.
c. Compression of the crests and pressure over the pubes (Patient lies on his unaffected side. Examiner then puts his forearm on the affected side and leans on it.)	Pain is absent.	Pain is present.

The treatment of lumbo-sacral or sacro-iliac strain is rest and support, later on heat and massage followed by education of the muscles to flatten the lumbar spine.

The rest is obtained by the application of adhesive strappings applied across the lower part of the back so as to include both iliac crests. The strips are three inches wide overlapping each other about one inch. It is best to include a piece of felt over the sacrum under the adhesive plaster. The strapping should extend to the lower ribs.

### (a) Erroneous Deflection of Body Weight in the Lateral Direction

(i) Slight deviation may give pain due to strain of the muscles. Real scoliosis (lateral curvature) sometimes produces pain. It is, however, not common. Scoliosis is easily diagnosed but treatment is complicated and prolonged and should be referred to an orthopedic surgeon.

(ii) Inequality in length of the lower extremity may cause backache. A difference of  $\frac{1}{8}$  to  $\frac{3}{4}$  inch exists in many normal people with-

disease. The diagnosis is easy since many other joints are involved and the treatment is the same as in general arthritis.

## II SPECIFIC ARTHRITIS

(a) *Tuberculosis of Spine (Pott's Disease)*—The pathology and diagnosis are well established. The disease is more common in children than in adults. The symptoms are pain, weakness and muscular rigidity with limitation of motion in the spine. Later on a "knuckle" appears. Tenderness is not a symptom. It is usually absent. Symmetrical paralysis and abscess formation are really complications and not symptoms. The radiographic findings are characteristic viz a pre-vertebral spindle-shaped shadow around the affected area in the entero-posterior view. There is bony destruction from the outset. Methods of treatment are well established, immobilization in plaster or braces, heliotherapy, operation by Hibbs or Albee methods.

(b) *Typhoid Spine*—The column is attacked by an infective process during convalescence. The bodies of the vertebrae, the intervertebral discs and the spinal ligaments are all involved. Widal test is positive. The condition does not often go to suppuration. The treatment is by prolonged rest and immobilization.

(c) *Acute Osteomyelitis*—This may occur in acute infectious diseases. The bodies or the arch of the vertebrae may be affected. There is a great deal of local pain and tenderness and inability to move the spine. Sometimes a deep seated abscess makes its way to the surface. Treatment consists of applying extension to the spine and opening the local abscess.

(d) *Syphilis of the Spine*—Usually found in the gummatous type. It is often very difficult to differentiate from tuberculosis, the most notable contrasts being less pain on motion, muscle spasm not striking especially in the uninvolved areas of the spine. Wassermann and the history help. Improvement after anti-syphilitic treatment is common. A rapidly developing painless deformity of the spine should always excite our suspicions of a Charcot arthropathy and lead to further search for symptoms that will substantiate the diagnosis.

## B TRAUMATIC BACKACHE

Traumatic backache is divided into (a) fractures, (b) sprains, (c) industrial lame back, (d) strains.

(a) *Fractures*—Serious types of fractures with the history of a severe accident and its concurring symptoms of a general fracture are not included in this series. The history with the marked disability and the definite radiograms will establish the diagnosis. However, one meets slight grades of unrecognized fractures which result in symptoms resembling arthritis. This is particularly true when there is a fracture of lam-

inae, transverse or spinous processes. It is a proper and important rule to have a radiograph taken of every injured spine no matter how trivial the injury is. The radiograph should be taken in two views—antero-posterior and lateral.

The treatment in general is recumbency usually on a Bradford frame. Then the spine is fixed by a corset or a back brace to be followed later on by massage and exercises.

(b) *Sprains of the Spine*—They are common in cervical and lumbar regions. Either the muscles or ligaments may be affected. When the muscles are affected the symptoms are intensified on the occasions when the muscles or group of muscles are put into action. The onset is usually sudden following a blow. Relieved by rest.

In injuries to the lumbar region there may be discomfort on coughing or sneezing or while riding over rough roads. Pain often radiates down the buttocks, thighs or even calves. Radiograms are negative. Hard to differentiate between muscle and ligamentous injury but differentiation is not essential.

*Treatment*—Applications of adhesive plaster strappings which should be prescribed for only three weeks, then gentle massage used. In cases of severe injury some support may be necessary.

Sir Robert Jones<sup>9</sup> suggests that optimism, explanation and re-education are the essential factors to successful treatment in this group of cases.

(c) *The Industrial Lame Back*—There are cases of back pain arising in persons who habitually hold and use their bodies in positions of mechanical disadvantage. This is true irrespective of the nature of the labor. Osgood<sup>1</sup> says "In hard working men, over forty, it is possible to discover the presence in the spine and other joints of what has been termed hypertrophic or osteo or degenerative arthritis." These may be revealed in the radiograms. The subjective symptoms of the early lesions of this type of arthritis may be nil, until some injury, even very slight, increases the local activity of the process. The symptoms are out of proportion to the nature of injury. The radiograms are usually the same.

*Treatment*—Rest. Proper posture. May be necessary to apply a plaster jacket for a short time, then physiotherapy.

Preventive treatment is important. Osgood<sup>1</sup> says "Although it has been sometimes opposed by organized labor, we believe a pre-employment physical examination by a physician who knows not only his medicine, but his mechanics would greatly lessen the number of back cases in industry. The labor unions should look upon this, not as an affront, but as an opportunity."

(d) *Lumbo-Sacral and Sacro-Iliac Strains*—These constitute the most common conditions of backache brought to the family physician. This used to be called lumbago. The cause is usually a sudden lifting of a heavy load. The pain is either dull or acute, localized in an indefinite way.

over the lower spine and hip radiating to one side down to the knee and leg. The pain is usually asymmetrical, sciatica is a frequent symptom. There is a great deal of pain in turning from side to side in bed. The spine often shows a deflection or tilt to one side.

For the orthopedic surgeon it is necessary to differentiate between the two but for the general practitioner it is sufficient to consider them as one.

Smith-Peterson<sup>7</sup> has ably given the differentiation between these lesions as follows:

This strapping is changed every five days for a few weeks then a brace is applied when barking and massage can be instituted.

(c) **ATTITUDINAL STRAIN—STATIC BACKACHE**—Jones and Lovett<sup>8</sup> introduced this term to define disturbances caused by the erroneous deflection of body weight causing strain to spinal muscles, joints and ligaments. The deviation may be (a) in the lateral direction or (b) in the anteroposterior direction.

## DIFFERENTIATION BETWEEN LUMBO-SACRAL AND SACRO-ILIAC

	<i>Lumbo-Sacral</i>	<i>Sacro-Iliac</i>
1 History	More comfortable on either side or back.	Cannot lie for any length of time on the side complained of.
2. Distribution of pain.	Projected or referred along the distribution of 5th lumbar and first sacral nerves, i.e., dorsum of foot, first toe, mesial aspect of the sole and heel and antero-lateral and posterior aspects of the lower leg, dorsum of the foot, 2nd, 3rd, 4th, and 5th toes and lateral aspect of the sole of the foot.	Pain referred along the fourth and fifth lumbar and first and second sacral nerves, i.e., posterior aspect of thigh as well as any part of the lower leg, usually antero-lateral and posterior aspect of the lower leg and lateral aspect of the ankle.
3 Examinations.		
A. Motions standing		
a. Flexion.	Lumbo sacral region rigid. Forward bending takes place at the hips and upper lumbar spine and dorsal regions.	Bends lumbar spine first then tilts the pelvis until the hamstrings become taut, then patient either stops or flexes his knee on the affected side.
b. Extension.	Lumbar spine kept rigid and bends knees	Lumbar spine moves and pelvis tilts backward.
c. Lateral flexion or side bending	No motion in lumbo sacral junction—Only motion in the dorsal and upper lumbar spine. Freer on the side away from the affected.	(1) In acute inflammatory cases motion is more limited toward the side affected. (2) In sacro-iliac strain the reverse is true.
B. Motions sitting	Flexion is limited.	Flexion is free.
C. Motions lying	Pain present. The lumbar spine cannot be flexed	Motion free except in severe cases
a. Passive flexion (flexing knee and hip)		
4 Special tests.		
a. Straight leg raising of affected side. (One hand should be under the patient's lower spine.)	Pain does not come on till after the lumbar spine begins to move.	Pain brought on before the lumbar spine begins to move.
b. Straight leg raising of unaffected side.	Pain is at the same level when the other leg is raised.	It is possible to bring the opposite leg to a higher level.
c. Compression of the crests and pressure over the pubes (Patient lies on his unaffected side. Examiner then puts his forearm on the affected side and leans on it.)	Pain is absent.	Pain is present.

The treatment of lumbo-sacral or sacro-iliac strain is rest and support, later on heat and massage followed by education of the muscles to flatten the lumbar spine.

The rest is obtained by the application of adhesive strappings applied across the lower part of the back so as to include both iliac crests. The strips are three inches wide overlapping each other about one inch. It is best to include a piece of felt over the sacrum under the adhesive plaster. The strapping should extend to the lower ribs.

### (a) *Erroneous Deflection of Body Weight in the Lateral Direction*

(i) Slight deviation may give pain due to strain of the muscles. Real scoliosis (lateral curvature) sometimes produces pain. It is, however, not common. Scoliosis is easily diagnosed but treatment is complicated and prolonged and should be referred to an orthopedic surgeon.

(ii) Inequality in length of the lower extremity may cause backache. A difference of  $\frac{1}{8}$  to  $\frac{3}{4}$  inch exists in many normal people with-

out their knowledge. In many people, on the contrary, a very slight difference due to accident or disease will give a great deal of pain in the back.

The treatment is of course to equalize the limbs.

(b) *Erroneous Deflection of Body in Antero-Posterior Direction*

We must remember that in the upright position the body is balanced against an anterior load. Any cause which increases the anterior load, necessitates greater muscular effort in maintaining the upright position and favors occurrence of this type of backache. Such causes are (1) large abdomen, (2) round shoulders, (3) flat feet which cause an inclination of the pelvis thus producing back strain and discomfort.

In general this form of backache affects the lower spine and occurs mainly during or immediately after standing, walking or sitting.

Cochrane<sup>9</sup>, a disciple of Goldthwaite, emphasizes that the two well marked variations from the normal spine are also predisposed to this form of backache.

(1) The congenital visceroptotic, narrow backed, long waisted, slender type of individual and (2) the thick set, broad-backed, heavy type. In the slender type of individual, relaxation of sacro-iliac joints are likely to be met with. In the heavy the lumbo sacral strain is most common.

(c) *Sacralization of the Fifth Lumbar Vertebrae*

Studies by O'Reily<sup>4</sup>, Moore<sup>5</sup> and others have proven that an abnormality in the transverse process of the fifth lumbar is very common. It predisposes to painful conditions and abnormal postures in the lumbo-sacral region. In some cases it is larger and much broader than normal. Sometimes instead of being bluntly pointed it is expanded or fan shaped. In these instances it may come in contact with the base of the sacrum especially during lateral flexion of spine. Irritation is set up, gradually a bursa is formed between the last lumbar and sacrum. If the condition is unilateral, the body is listed to the other side. Sometimes the transverse process fuses with the ilium or sacrum and is called sacralization of the fifth lumbar. These are often associated with strain and osteo-arthritic changes in the lumbo-sacral and sacro-iliac joints. The osteo-arthritic changes reduce the foramen through which the anterior division of the fifth lumbar nerve emerges. When it is pressed upon, referred pain to the knee and leg is produced.

Subluxation or relaxation of sacro-iliac joints is not as common as it was formerly believed. Outside of pregnancy or after very severe or

crushing trauma its existence is not well established.

*Diagnosis*—Sir Robert Jones<sup>8</sup> emphasizes and we agree that "there is no more difficult problem in diagnosis than the recognition of static backache and its differentiation from other types."

Treatment of static backache is general and local. The patients are usually below par, hence the general condition should be built up.

*Local Treatments*—Strapping, then a sacro-iliac compressor and exercises. Very large transverse processes should be removed. If errors in the lower limbs exist, they should be corrected. Baking with electric light or alpine lamp is helpful but it can not supplant fixation.

*Exercises*—(1) Spinal motion—flexion, extension, lateral bending and rotation. (2) Developing and strengthening of the muscles of abdomen, lateral abdominal walls (flanks) and back.

*Radiography of the Sacro-Iliac Joints*—Osgood<sup>10</sup> states boldly and acutely "The separation of sacro-iliac and pubis may often be within normal limits and has nothing to do with the symptoms. We may know that the displacements demonstrated (especially in medico legal cases) are often due to the asymmetry of the X-ray tube and not to the asymmetry of the patient. It depends therefore for whom the physician testifies."

To determine the cause of separation of sacro-iliac and pubis, plates should be taken at various angles, taking into consideration anomalies before more definite information can be obtained. A radiograph is of value in ruling out injury or disease of bone, determining the extent of arthritic changes, if present, and detecting congenital anomalies.

#### D BACKACHE DUE TO NEOPLASM

Sarcoma, osteoma and metastasis are found. Hard to diagnose them. One has to depend mainly on the general symptoms. It is common in spinal cord tumors and malignant diseases of the bones. We can alleviate the symptoms only slightly by support.

#### E BACKACHE DUE TO UTERINE, PELVIC AND ABDOMINAL CONDITIONS

Uterine trouble is more often overestimated than underestimated. However in women backache of pelvic origin is often indistinguishable from static backache and the gynecologist should be consulted. In case of young girls it is safer to assume the cause to be static.

#### 4 GENERAL OUTLINE OF EXAMINATION

Osgood and Morrison<sup>1</sup> advise the following routine in examining a patient with backache.

1 Strip the patient and note the general body

- form and the muscular development and tone
- 2 Patient standing
  - a General statics, body posture in relation to the centre of gravity, abdominal contour, weight bearing lines of the feet
  - b Note exaggeration of the normal curves of the spine, abnormal curves, deviations
  - c Motions of the spine, active and passive
  - d Muscle spasm, general and local
  - e Chest expansion
- 3 Patient sitting
  - a Motions of the spine, active and passive. (In lumbo-sacral cases, forward flexion will be still limited, in sacro-iliac it will be free because of support of the pelvis and relaxation of the hamstrings)
  - b Reflexes, disturbances of sensation and motion in the limbs
  - c Condition of the circulation, blood pressure, heart, lungs, tonsils, teeth, etc
- 4 Patient in dorsal recumbency
  - a Measurements of the length of the lower limbs and the comparative size of the calves and thighs
  - b Contours of all joints by inspection and palpation
  - c Motions of all joints, active and passive
  - d Flexion of thighs on pelvis with knees bent. (In lumbo-sacral lesions, this may be expected to be painful, in sacro-iliac, not painful because the pelvis moves more as a whole)
  - e Flexion of the thighs with the knees straight, hand beneath lumbar spine to detect relation between expression of pain and movement spine (Helpful in discriminating between low spinal and sacro-iliac lesions)
  - f Ability to assume and symptoms caused by the opisthotonos position (Agnew's sign)
  - g Abdominal palpation Special reference to faecal masses in colon
  - h Points of tenderness, especially the pubic symphosis
- 5 Patient in lateral recumbency
  - a Symptoms caused by lateral compression of crests Care taken to have patient lie on side of lesion and to sustain the pressure on the crests If painful, suggests sacro-iliac lesion
- 6 Patient in ventral recumbency
  - a Contours of spine, pelvis and hips
  - b General and local muscle spasm
  - c Points of tenderness in back and along nerve trunks Note especially coccygeal, sacral, sacro-iliac, posterior-superior spines, ilio lumbar ligaments, lumbo-sacral joints and spinous and transverse process tenderness
  - d Symptoms and signs elicited by extreme flexion of the knees
  - e Symptoms and signs elicited by hyperextension of the thighs
  - f Anatomic relationships of bony prominences
  - g Rectal and prostatic examination
- 7 In what position in recumbency is patient most comfortable? (In sacro-iliac lesions, for example, the patient is usually uncomfortable if he lies long on the side of the lesion A lumbo-sacral case is usually comfortable lying on either side or on the back)
- 8 Roentgenological examination
  - a Antero posterior and lateral views of spine well above and below suspected region
  - b Stereoscopic views of the lumbo-sacral and sacro-iliac regions
- 9 Such laboratory examinations as are considered likely in the individual case to yield important data Urine, blood, spinal fluid, Wassermann, etc

## 5 CONCLUSIONS

1 Backache requires the most careful examination and differentiation No hasty diagnosis should be made

2 There is no more difficult problem in diagnosis than the recognition of static backache and its differentiation from other types

3 The diagnosis of railroad spine, functional spine, relaxation of sacro-iliac, sciatica or lumbago should rarely be made

4 Abnormalities in the vertebrae both in number and shape are found even in apparently normal individuals These anomalies predispose to backache but are not the real cause

5 Any injury of the spine should be treated as a fracture unless proven otherwise Even slight and trivial traumata should be subjected to careful radiographs and study

6 Radiography of the spine—two views should be taken of every case—antero-posterior and lateral views, to rule out injury or disease of bone, determine the extent of arthritic changes if present and detect congenital anomalies Separation of sacro-iliac and pubis cannot be definitely determined by the radiographic plates

7 The rules and principles for acquiring

and maintaining the proper mechanics of the body in its anatomic correct position are few and should be memorized by every physician

8 In spondylitis deformans and hypertrophic arthritis the spine should be immobilized in a plaster of Paris jacket. The source of infection should be sought and removed if possible

9 Osteo-arthritic changes found at the lumbo-sacral and sacro-iliac joints reduce the foramen through which the anterior division of the fifth lumbar nerve emerges. When it is pressed upon, referred pain to the knee and leg is produced

10 Tuberculosis of spine is easier to diagnose than the other forms of specific arthritis and the physician should be well versed in its main clinical features

11 Fractures of spine should be treated with immobilization in plaster of Paris jackets or double plaster shells and Bradford frame. If cord complications are present it should be watched for a very long time to decide whether or not operation is necessary

12 Sprain of spine should be treated by strapping, then massage and exercises

13 Lumbo-sacral and sacro-iliac strains should be treated by adhesive plaster strap-pings then baking, massage and exercises followed by education of the muscles to flatten the lumbar spine

14 In static backache the etiological factor should be corrected hence flat feet or inequality of feet should be remedied, the posture improved by proper exercises and temporary support if necessary

## REGULATION OF MASSAGE BY NEW YORK CITY DEPARTMENT OF HEALTH

By S. DANA HUBBARD, M.D., NEW YORK, N. Y.

IN the early part of 1916, the attention of the authorities was called to violations of the Medical Practice Act and various irregularities relating to massage as it was being operated in the City of New York. These conditions brought about an ordinance (Code of Ordinances, Chapter 14, Article 1, Article 15) causing all persons practicing massage to be registered with the Department of Licenses annually, the fee for which was \$3.00 for each operator and \$10.00 per year for each massage institute, license being renewable on December 1st of each fiscal year. A later amendment required the presentation of certificates of training. We would therefore quote the Statute (Ordinance 171) which is as follows:

"Schools of massage duly licensed under this ordinance shall be recorded in the office of the Commissioner of Li-

censes upon receipt of a certificate signed by the Commissioner of Health of the City of New York, certifying that, in his opinion, *the course of instruction in the school is adequate and the staff competent to give the necessary instructions in massage*"

Accordingly, applicants for massage licenses are referred by the Department of Licenses to the Department of Health for visæ of the credentials of these applicants. In the *Boston Medical and Surgical Journal* of December 9, 1926, volume 195, number 24, there is an interesting article that is very comprehensive relating to "Physiotherapy Its Use by the General Practitioner," by James Warren Sever, M.D., F.A.C.S., wherein the subject of massage is very comprehensively and informally treated from the medical point of view.

The Statute of the City of New York (Section 175, Definitions) states that, "A person who applies manual or mechanical massage or similar treatment to the human trunk or limbs shall be deemed to be within the terms of this ordinance a massage operator, but no person comprehended within the provisions of Section 219 of the Sanitary Code, entitled nurses, or Section 173 of the Public Health Law, relating to osteopathy, shall be deemed to be intended within the provisions of this ordinance."

By practical application of this Statute, officials have interpreted that barber shops and beauty parlors who limit their hand or mechanical manipulation to the face and head are exempted from the operation of this statute

Establishments which have in their windows, exposed to public view, a sign "massage" have been informed either to secure an institute license or remove the misleading sign from public gaze which is violating this statute through such use

With the recently amended Medical Practice Act of May, 1926, wherein there was included a physiotherapy clause, complications have arisen as to interpretation of the two acts. Of course, legally it is understood that the state act takes precedence and is superior to the local or Municipal Statute, but what constitutes "mechanical manipulation" and what constitutes "physiotherapy," in the use of certain devices—electrical vibrators, electrical heat lamps and similar appliances—has caused some confusion to the authorities in the regulation of masseurs

For the information of the public, we would, therefore, attempt to interpret the massage ordinance in order that the public may understand the point of view of the Commissioner of Health in the operation of the Statute as required in the section relating to his supervision

Manual manipulation, technically and scientifically applied, supplements the work of the physician. The use of the electrical vibrator, as is done in barber shops and beauty parlors frequently, would be, in our opinion, proper application of massage by a masseur

#### WHAT CONSTITUTES MASSAGE?

It generally is recognized that massage has five definite, well recognized methods of application

- 1 Stroking, effleurage
- 2 Kneading, petrissage
- 3 Friction, firm deep circular movements for breaking up adhesions
- 4 Tapping, tapotement
- 5 Vibration, which may be done by the finger tips or the palm of the hand, used as a hammer

In our opinion, this is, as a rule, better performed by the use of an electrical vibrator either directly applied or through the hand of the oper-

ator, and this use would not violate the state act regarding Physiotherapy

The principle purpose of massage is either muscle training or re-education of muscles. This may be performed through one of the following methods

(a) Improving the circulation and through this the nutrition

(b) Through exercise passively administered to maintain muscle tone, thereby preventing the degeneration of muscle fibre atrophy from disuse or in the case of adhesions in tendons or joints to aid in breaking adhesions and restoring thereby the function of the part

(c) To strengthen weakened muscles whose nerve supply is unimpaired

(d) To aid in co-ordinating nerve centers where a partial destruction has occurred. Here re-education by habit, acquired through massage, increases the strength of not only the whole muscle but of the limb

In performing this function, with all muscle training, intelligent examination must be made to *diagnosicate indications*, because simply applying massage unintelligently to a limb and not to a specific group of muscles affected, will not make massage helpful, but, on the contrary, might do harm, through over exercising a weakened group of muscles in need of rest. If the wrong group of muscles are exercised and over-developed from such practice, deformity may be caused and the likelihood of causing deformity is great in zealous patients especially the young

After determining what groups of muscles are to be developed, the type of exercise best suited to the muscle, the amount of exercise is very essential in this problem

#### WHO SHOULD GIVE MASSAGE?

Good massage properly applied means adequate training and proper anatomical knowledge. These two requisites should always go together. One of the causes of failure of massage, as an aid in healing, has primarily been due to the failure to distinguish, between scientific massage properly applied and unskilled rubbing which merely requires human strength and dexterity

Physicians, as a class, know practically nothing about massage, principally from the want of training

A person properly trained in physical therapeutics and massage can give better treatment, get better results with less waste of time than can either physicians or untrained so-called rubbers or massage attendants

No massage should be given in any case following an injury or fracture unless the instruction for such treatment is under the supervision and direction of a surgeon and then only in such doses and at such intervals as the doctor prescribes

Manipulation of joints or parts following fractures or injuries should never be undertaken without express direction from the surgeon, otherwise harm may result and the patient made to suffer unnecessarily

It is a good rule always to follow that when forcible passive motion causes pain, "Don't do it" The presence of pain and irritable joint following a sprain, fracture or injury, leads only to the aggravation in the symptoms What such a part needs is rest, possibly fixation The bad effects of forcible motion are seen best in cases of injuries of the elbow, especially in children

It is hoped that we have made ourselves clear in regard to the dangers applying to massage not supervised and the use of massage by the untrained Muscle atrophy is a real danger and must be combated and this can be successfully done in the hands of the expertly trained masseur without the use of which technical results almost invariably will be disappointing and convalescence tediously prolonged

Physicians are, therefore, earnestly requested in both hospital and private practice to watch the application of the position of massage in New York

## THE PRIVATE PRACTITIONER AND PREVENTIVE MEDICINE \*

By EDWARD H. MARSH, M.D., ALBANY, N. Y.

Secretary, State Department of Health

**M**ANY do not realize that it was during the eighteenth century that the medical profession began to show an interest in preventive medicine Some of the achievements at that time which, mind you, were not initiated by governmental boards but by individual physicians, were the reformation of obstetric practice, the study of infant mortality, the establishment of dispensaries, hospitals and medical schools, industrial welfare work, notification and disinfection as a means of controlling communicable diseases and the systematic study of epidemiology

It took considerable effort on the part of William Hunter to get the medical profession to recognize obstetrics as a respectable medical procedure, and it was many years before a physician who did obstetric work was considered eligible for membership in a medical society Hunter practiced preventive medicine when he preached natural delivery instead of forceps It was he who used to exhibit his forceps covered with rust to indicate that he never used them Oliver Wendell Holmes, the great poet, essayist and medical teacher, was one of our pioneer epidemiologists when he discovered the "contagiousness of child-bed fever" His essay on that subject is one that every physician should read Holmes was not a public health official He was a practicing physician Credé was an obstetrician, yet his method of preventing ophthalmia of the new-born is one of the most valuable preventive measures practiced

I merely mention these historic incidents to show that preventive medicine is not the duty of some governmental agency only All of you, consciously or unconsciously, are practicing preventive medicine every day of your lives When you put on rubber gloves for

delivery you are possibly saving a life, when you allow nature to take its course and avoid, if possible, a forceps delivery, you are not only avoiding a possibility of infection, but you are lessening the chances of tear with subsequent gynecological pathology and perhaps chronic invalidism on the part of the mother When you direct the pregnant woman as to her diet, you are preventing the illness of the child to-be, when you prescribe cod liver oil and orange juice for the infant, you are practicing preventive medicine by insuring the child against rickets and scurvy, when you administer salvarsan to the case of early syphilis, you are not only practicing curative medicine, but you are preventing the subsequent infection of others from that source I could go on indefinitely calling your attention to instances of preventive medicine in your practices, but I shall add only one more—when you treat intelligently one of the acute infectious diseases such as diphtheria, scarlet fever or acute rheumatic fever (if that be included in such a group) you are practicing preventive medicine as well in that you are lessening the chance of subsequent cardiac involvement

Public health is merely the aggregate state of health of each individual in the community Public health then should not be regarded by physicians as a somewhat uninteresting function of a government bureau or department, the medical profession in their own practice should adopt all methods directly intended to prevent disease

The functions of the physician in preventive medicine may be divided for purposes of discussion into three main groups Let us consider first the diseases dependent on sanitary conditions You may think that here is a group of diseases the control of which is essentially and solely the function of govern-

\* Address to Staff of Nassau Hospital, April 14, 1927

mental agency True, yet the medical profession has certain responsibilities You, by virtue of your profession and education are or should be leaders in your respective communities, especially is this so in the smaller municipality As members of the medical profession I am sure none of you would desire to revert to the days when you were treating six to ten cases of typhoid fever every day during the late summer and fall, nor would you want to go back to the time when every summer you signed certificate after certificate registering the death of babies from diarrhea Improvement in these conditions has been brought about by better water and milk supplies, due in no small measure to the activities of physicians Here in parts of this country today sanitation is being grossly neglected and it is the duty of the medical profession to lead the way to better conditions In his daily contact with patients the physician has a better opportunity for instructing the general public on such matters than any other individual.

The second function of the physician in disease prevention has to do with infectious diseases per se Here you have several duties laid down by statute and regulation The disease must be reported promptly to the health authorities in order that proper precautions to prevent further spread of the disease may be taken There is another reason for prompt reporting—that immediate steps may be taken to find the original source of the disease Here I feel there is an opening for better work by the medical profession as a whole The sooner an epidemiological study can be started, the better are the chances of bringing it to a successful conclusion Briefly, to get at the source of an outbreak of a communicable disease, it is necessary to find something in common to a group of cases of that disease If there are delays in reporting the individual cases, it means that the source of infection is at work for so much longer a time The tendency of physicians is to wait until a diagnosis is firmly established before the case is reported—legally of course this procedure cannot be questioned—but if cases of epidemic disease were reported when the physician is reasonably sure of his ground, some additional cases could unquestionably be prevented

The physician has another duty with reference to communicable disease which, I am sorry to say, is not infrequently neglected I refer to the examination of family contacts I suppose this is rarely overlooked in diphtheria or scarlet fever, but how many physicians advise such an examination when they find a case of pulmonary tuberculosis?

In this connection also should be mentioned the duty of the physician attending a child

suffering with either measles or whooping cough when there are children under three in the household It may be advisable to administer to such young children convalescent measles serum or pertussis vaccine In any event, the physician should instruct the parents as to the need for careful observation of the young children and the necessity of putting them to bed immediately upon the appearance of the earliest manifestation of the disease

Still another function of the family physician is to teach his patients to isolate every sick child in the family until it is definitely proven that the illness is not of an infectious nature If all did this, there would be far fewer secondary family infections

Lastly in considering the group of infectious diseases we come to the administration of specific prophylactic measures No physician, qualified to be such, today questions the efficacy of vaccination to protect against smallpox and typhoid fever None will advise against it if the patient asks for it, yet how few there are who take the aggressive, so to speak, and urge their patients "to come around to the office and get it" Last year, when smallpox appeared in this county, I was amazed to find the large number of unvaccinated children Of course, you may rightly say this is a parental responsibility I do not question that, but I do feel that the physicians should take the opportunity when visiting a family for any cause to urge vaccination What I have just said also holds good for toxin-antitoxin to prevent diphtheria The health authorities can hold campaign after campaign, clinic after clinic, but in the final analysis the extent of immunization to diphtheria will depend on the activity of the family doctor in urging it I believe that it is a proper procedure for a physician to write to the mother of a child, when that child is six months old, and advise her to have the child immunized

The third function of the physician in preventive medicine includes measures which he not infrequently overlooks The practicing physician is in the best possible position to render service to his patients in prenatal, maternal and infant hygiene The opportunities for instructing mothers in these phases of personal health are almost innumerable Is there any ethical reason why after attending a mother in her confinement and puerperium, the physician should not insist that the baby be brought to him for regular periodic examination? If it be granted that this is proper practice, why is it not equally proper to advise further periodic examination during early childhood? But why stop there—let such examinations continue throughout adolescence and adult life

This brings us naturally to the subject of periodic physical examinations of all persons. That this is a measure to be advocated is unquestionable, but the average physician of today is trained to interpret signs and symptoms in the obviously sick person rather than to look for the abnormal in an individual who feels "perfectly well." In my opinion the periodic physical examination, the so-called "health examination," cannot reach its maxi-

mum value until the medical colleges alter their curricula and provide the proper and necessary training for this purpose.

In the meantime, however, the present day physician with the means at his command can accomplish worth while results along the lines I have attempted to sketch very briefly, and thereby add to the peace and happiness of his community and of the state.

## CHRONIC APPENDICITIS

### A CLINICAL AND PATHOLOGICAL STUDY FROM THE LENOX HILL HOSPITAL

By ROBERT C SCHLEUSSNER, M D, NEW YORK, N Y

THE object of this study was to determine whether definite chronic inflammatory reactions of the appendix gave rise to a group of symptoms and clinical findings which could be grouped together as forming a definite chronic clinical picture. Such a clinical picture might then be properly designated as "chronic appendicitis."

For the purposes of this paper, we would limit the term "chronic appendicitis" to those clinical syndromes in which there is a more or less continuous symptomatology of at least two weeks duration. It is realized that recurrent attacks of acute appendicitis with no interval symptoms, are an established fact and the term "chronic appendicitis," as above defined, specifically excludes these cases.

The approach to the subject was made from the study of the pathological lesion. It becomes necessary then, to describe the lesion which was the basis of the study. The specific description may be prefaced by the general statement that appendices were sought out which had the mildest possible lesions which were still definitely inflammatory. The serosa and muscularis usually showed a greater or less degree of fibrosis, together with oedema and congestion. There was always some degree of inflammatory cellular infiltration of these same coats. The infiltration consisted of varying proportions of polymorphonuclear leucocytes, lymphocytes, eosinophiles, plasma cells and mast cells and varied considerably in intensity. Appendices showing only highly acute and intense inflammatory reactions were not considered clinically. We also excluded from clinical consideration, appendices in which the pathological department had made a diagnosis of chronic catarrhal appendicitis or chronic obliterative appendicitis. For in the former class (chronic catarrhal appendicitis) are placed appendices with minor changes, confined mostly to the submucosa and mucosa and open to varying interpretations, according to the standard of normal adopted. The latter class (obliterative ap-

pendicitis), while definite from the pathological anatomical standpoint, is of doubtful pathogenesis and would require separate consideration.

In fixing the standards as above, it is realized that we are avoiding the question of the relation of the doubtful lesions of the appendix to clinical symptoms. The comparison of symptoms with the pathological lesion under the conditions defined is only a part of the subject of so-called chronic appendicitis, but it is believed to form a basis upon which consideration of the less well defined lesions of the appendix must rest. Our object, as previously stated, was to determine whether or no a clinical chronic appendicitis ever rested upon an unquestionable chronic inflammatory lesion in the appendix, how often it occurred and what the symptomatology and findings were under those conditions.

With this object in view, the study was approached by reviewing the records of the pathological department during the two years, 1923 and 1924. All appendices diagnosed anatomically as chronic appendicitis, subacute appendicitis, or acute and chronic appendicitis (altogether some 97 in number) were selected for study. In many instances the acute reaction was so intense as to mask any fibrosis and these appendices were excluded from further study. In a few instances the lesion was confined almost entirely to the submucosa and mucosa and these appendices were excluded by the standard assumed. With the above appendices excluded there remained 37 specimens in which the inflammatory reaction was so mild or the fibrosis so marked that one might fairly assume the process to have been subacute or chronic in point of time.

The next step taken was the review of the clinical records of the patients whose appendices had shown these assumed subacute or chronic changes. From the clinical aspect it was possible to form three distinct groups.

Group 1 This group was comprised of the cases having the history and physical findings

of the usual case of acute appendicitis. The symptoms varied in duration from 12 hours to 2 weeks. None of these patients had had any previous attacks. This group was by far the largest, including 21 cases.

**Group 2** This group was comprised of the cases having the same time duration as those in group 1. But these patients had had one or more previous attacks at varying time intervals. In no case, however, had there been any symptoms in the intervals between attacks. This group included 12 cases.

**Group 3** This group was comprised of cases that had had symptoms of at least two weeks duration and this is the group that we wish to consider in detail. The clinical syndromes occurring here are the only ones which could, by definition, be considered under the general heading of chronic appendicitis. The group contains but 4 cases and the longest history is of only six months duration. The detailed histories follow.

**Case 1** History No 7501 Female, age 34. Four months previous to admission she had had an attack of abdominal cramps. These lasted several days and during this time the patient vomited once. Thereafter she had more or less continuous pain on the left side of the abdomen. At irregular intervals there was belching of gas and sour eructations occurred. Eight days ago the patient began to have severe persistent diffuse abdominal pain. She vomited once. Constipation has always been present.

Examination showed tenderness in the right upper and lower and the left lower quadrants but only on deep pressure. The temperature on admission was 101 but dropped to normal after several days in bed. Blood count showed 14,500 white cells, with 89% polymorphonuclears. X-ray examination of the gastro-intestinal tract, including a colon bismuth enema, showed tenderness over the hepatic flexure and some apparent fixation of the colon.

At operation the appendix was found bound to the lateral abdominal wall and the omentum was adherent over the caecum and appendix.

**Pathological Report**—The appendix was 6 cm long and 1 cm in diameter. The serosa was roughened and covered by hemorrhagic adhesions in places. The lumen is patent, dilated in the proximal 5.5 cm and obliterated distal to this. The wall measures 2 to 3 mm in thickness. The mucosa is pale and ragged. The lumen contains soft faecal material. Microscopically the serosa shows a well marked and quite uniform fibrosis, with quite well developed collagen fibrils. There are many small blood vessels present and throughout there is a diffuse cellular infiltration consisting mostly of plasma cells, though a small proportion of lymphocytes and polymorphonuclear leucocytes are present. There is a distinct

oedema present. The muscularis shows no fibrosis but exhibits a mild though distinct diffuse cellular infiltration of eosinophiles, with a few plasma cells and lymphocytes. The submucosa and mucosa showed no marked inflammatory changes.

**Case 2** History No 5384 Female, age 23. Five weeks before admission patient began to have a sticking pain in the right lower quadrant and generalized abdominal cramps. The pain was especially well marked on arising in the morning. It was relieved by eating, but 15 minutes after eating burning pain would develop in the epigastrium and would be accompanied by nausea and regurgitation. The patient was treated for some weeks with alkaline powders and a special diet, but did not improve. She had never had an attack similar to the present one.

Physical examination was entirely negative excepting slight tenderness in the right lower quadrant. X-ray examination of the gastrointestinal tract showed a normal stomach and duodenum, but there was a small six hour retention in the stomach. On the 24 hour plate a possible appendix was visualized, but nothing abnormal was indicated. No blood count was charted.

At operation the appendix was described as tortuous and somewhat elongated. The meso-appendix was adherent to surrounding structures. The plevus and upper abdomen were explored and found normal.

**Pathological Report**—The appendix was 6 cm long and 1 cm in diameter. The serosa was pale and glistening, though the vessels were injected. The wall was not thickened and the lumen was patent throughout. The mucosa seemed normal. Microscopically the serosa showed a very marked thickening due to fibrosis of a recent type, with numerous hemorrhages and a profuse cellular infiltration consisting of polymorphonuclear leucocytes and lymphocytes. The muscularis also showed a well marked cellular infiltration, predominantly eosinophilic. Sumbucosa showed a moderate eosinophile infiltration.

**Case 3** History No 7408 Female, age 44. Six months ago the patient had pain in the abdomen which lasted two days. It subsided but returned in two weeks and has been present every day since. It has no relation to meals and does not radiate. It disappears when she lies down and is worse after she has been on her feet all day.

Physical examination revealed slight rigidity and tenderness in the right lower quadrant. There is a first degree prolapse of the uterus with a rectocele and cystocele. Temperature is normal. Blood count showed 14,000 leucocytes with 66% polymorphonuclears, 24% lymphocytes, 2% eosinophiles and 6% transitionals. X-ray examination of the gastrointestinal tract was negative except for slight tenderness over the caecum.

This brings us naturally to the subject of periodic physical examinations of all persons. That this is a measure to be advocated is unquestionable, but the average physician of today is trained to interpret signs and symptoms in the obviously sick person rather than to look for the abnormal in an individual who feels "perfectly well." In my opinion the periodic physical examination, the so-called "health examination," cannot reach its maxi-

mum value until the medical colleges alter their curricula and provide the proper and necessary training for this purpose.

In the meantime, however, the present day physician with the means at his command can accomplish worth while results along the lines I have attempted to sketch very briefly, and thereby add to the peace and happiness of his community and of the state.

## CHRONIC APPENDICITIS

### A CLINICAL AND PATHOLOGICAL STUDY FROM THE LENOX HILL HOSPITAL

By ROBERT C SCHLEUSSNER, M D, NEW YORK, N Y

THE object of this study was to determine whether definite chronic inflammatory reactions of the appendix gave rise to a group of symptoms and clinical findings which could be grouped together as forming a definite chronic clinical picture. Such a clinical picture might then be properly designated as "chronic appendicitis."

For the purposes of this paper, we would limit the term "chronic appendicitis" to those clinical syndromes in which there is a more or less continuous symptomatology of at least two weeks duration. It is realized that recurrent attacks of acute appendicitis with no interval symptoms, are an established fact and the term "chronic appendicitis," as above defined, specifically excludes these cases.

The approach to the subject was made from the study of the pathological lesion. It becomes necessary then, to describe the lesion which was the basis of the study. The specific description may be prefaced by the general statement that appendices were sought out which had the mildest possible lesions which were still definitely inflammatory. The serosa and muscularis usually showed a greater or less degree of fibrosis, together with oedema and congestion. There was always some degree of inflammatory cellular infiltration of these same coats. The infiltration consisted of varying proportions of polymorphonuclear leucocytes, lymphocytes, eosinophiles, plasma cells and mast cells and varied considerably in intensity. Appendices showing only highly acute and intense inflammatory reactions were not considered clinically. We also excluded from clinical consideration, appendices in which the pathological department had made a diagnosis of chronic catarrhal appendicitis or chronic obliterative appendicitis. For in the former class (chronic catarrhal appendicitis) are placed appendices with minor changes, confined mostly to the submucosa and mucosa and open to varying interpretations, according to the standard of normal adopted. The latter class (obliterative ap-

pendicitis), while definite from the pathological anatomical standpoint, is of doubtful pathogenesis and would require separate consideration.

In fixing the standards as above, it is realized that we are avoiding the question of the relation of the doubtful lesions of the appendix to clinical symptoms. The comparison of symptoms with the pathological lesion under the conditions defined is only a part of the subject of so-called chronic appendicitis, but it is believed to form a basis upon which consideration of the less well defined lesions of the appendix must rest. Our object, as previously stated, was to determine whether or no a clinical chronic appendicitis ever rested upon an unquestionable chronic inflammatory lesion in the appendix, how often it occurred and what the symptomatology and findings were under those conditions.

With this object in view, the study was approached by reviewing the records of the pathological department during the two years, 1923 and 1924. All appendices diagnosed anatomically as chronic appendicitis, subacute appendicitis, or acute and chronic appendicitis (altogether some 97 in number) were selected for study. In many instances the acute reaction was so intense as to mask any fibrosis and these appendices were excluded from further study. In a few instances the lesion was confined almost entirely to the submucosa and mucosa and these appendices were excluded by the standard assumed. With the above appendices excluded there remained 37 specimens in which the inflammatory reaction was so mild or the fibrosis so marked that one might fairly assume the process to have been subacute or chronic in point of time.

The next step taken was the review of the clinical records of the patients whose appendices had shown these assumed subacute or chronic changes. From the clinical aspect it was possible to form three distinct groups.

Group I This group was comprised of the cases having the history and physical findings

ting any of the problems which arise in the four hundred pages of "Domestic Duties, or Instructions to Young Married Ladies on the Management of Their Conduct in the Various Relations and Duties of Married Life," an amazing catechism written by a Mrs William Parkes

Mrs L, the pupil, remarks, "The choice of a medical attendant is the subject on which I now wish to know your opinion" The opinion is immediately forthcoming

"Nothing is of greater importance than this choice, and yet there are few events in life which are more regulated by accident Locality, a fashionable reputation, or the recommendation of a gossiping acquaintance, may bring an individual into your house, to whose skill your life is to be intrusted, and upon whose integrity your character is to be reposed, upon such slight grounds do we not infrequently place our confidence, and then are astonished if we find it has been given to an unworthy object

"The first object is to ascertain that the person you are about to employ has been regularly educated, that he is a man of strong intellect, discrimination, and good sense Without these qualities, a good education will avail him little, it cannot give him either acuteness of judgment, by which he alone could be enabled to observe the nice distinctions which characterize diseases and to display individual skill, when circumstances occur to require a difference in management from the usual

"Great danger may arise from calling in ignorant and irregular practitioners Such men establish their reputation by the boldness of their measures, which kill rather than cure. It is surprising that so much infatuation prevails in this country, in favor of these irregular practitioners, many of whom, if they have any knowledge at all, must have attained it by intuition, yet, people will have the folly to resort to them, and to reject men whose lives have been spent in alternate study and practice It is not just to the regular practitioners to encourage these spurious offsets, and it is injurious to society to do anything which shall increase their numbers, or give them confidence with the multitude

"The medical man should be firm in his determinations, but not obstinately so with sufficient liberality and candour, he should be willing to listen to any suggestion and recommendation even if it proceed from an unprofessional person His manner should be cool and collected nor should any unforeseen turn in the progress of a disease, ever deprive him of his self possession His whole deportment should entitle him to respect and confidence which should give weight to his persuasive powers, when called into action by an untractable patient He should be cheerful and mild, gentlemanly in his habits, and possess a large store of patience to enable him to

listen, even with the appearance of interest, to all the details of an invalid's complaint"

At this point Mrs L remarks that in drawing this *beau ideal* of a medical man, conversational powers should not be omitted Mrs B accepts this as a just observation, and proceeds

"After professional ability, the next point to be ascertained is respecting the moral character and the nice sense of honour maintained by the person to whom you are about to give access to your abode at all times From his deficiency in these important qualities, may result serious inconveniences

"The worst traits in the professional character, are the habit of gossiping and being addicted to scandal Possessing these failings, he carries with him from one house to another an influence not less malignant nor less fatal to happiness than the worst of pestilential diseases He sows the seeds of dissension, distrust, and illwill among relatives, friends, and neighbors"

Such is the inquisition awaiting the aspiring physician Can he be blamed for a slight retaliation? Mrs L reports

"I have heard a medical man complain of the ignorance, and even imbecility, which he meets with in many houses, in which a female cannot be found, who can or will dress a wound or blister, or who knows how to foment a limb or apply a poultice, and that these and many other little offices, which can with most propriety be performed by a wife or a mother, are usually done by the rude and careless hands of a hired attendant Do you not think this kind of ignorance is disgraceful in a well educated female?"

Mrs B, deeply grieved, admits this lamentable truth, and adds, "I have, I am sorry to say it, seen some ladies object to do all these little services to an invalid from over delicacy, and have preferred the indulgence of weak feelings and false notions, to the humane desire of comforting and alleviating the pains of an invalid friend Ignorance from this cause is, indeed, disgraceful"

But if the medical man resents the apprehension which he and his talents arouse he may take consolation, perhaps, in the fact that his accomplice, the nurse, is viewed with positive consternation

Mrs L comments, "It is very singular, that in the present state of society when improvement has extended itself to every rank and profession, that this class of people (nurses) has remained stationary in mind manners and prejudices Indeed, were I to describe a sick nurse from those I myself have known, I should say that infirmity, ignorance, grossness of habit and manners, want of feeling, except where her own interests are concerned, want of cleanliness and a contemptible disposition to intrigue with her wants form the chief of her characteristics

This case was seen in consultation by the surgeons who believed the symptoms were due to the pelvic condition

The operators notes do not describe the operative findings, but it seems probable from the operative description that the appendix appeared normal

*Pathological Report*—The appendix was 4 cm in length and 8 mm in diameter. The serosa was roughened and somewhat injected. The wall measured 2 to 3 mm in thickness. The lumen was constricted up to 2 cm from the distal end where it opened into a cyst-like cavity about 7 mm in diameter. The mucosa appeared atrophic. Microscopic examination showed a moderate thickening of the serosa in places due to a fibrosis of a rather mature type, with small hemorrhages and a few scattered lymphocytes. The muscularis showed a rather scant though definite cellular infiltration consisting of eosinophiles and lymphocytes. There is a mild but definite fibrosis of this coat. The submucosa shows no definite change. The mucosa is atrophic in the dilated area.

Case 4 History No 2291 Female, age 15. For the past three weeks the patient has had attacks of pain in the right lumbar region. The pain was cramplike in character and did not radiate. It was accompanied by nausea and vomiting. The pain comes and goes at irregular intervals. The patient has been constipated since the onset of the present illness. Two years ago there was an attack similar to the present one.

Physical examination showed moderate tenderness over McBurney's point on deep pressure. Temperature and blood count were normal.

At operation it was noted that the appendix was somewhat inflamed, but there were no adhesions.

*Pathological Report*—The appendix was 51 cm long and 8 mm in diameter. The vessels of the serosa were injected in places. The lumen was narrowed in places. Microscopically the serosa showed patches of well marked fibrosis with thin walled vessels and quite abundant lymphocytic infiltration. The muscularis showed an occasional eosinophile along the course of the blood vessels with occasional small groups of lymphocytes. The submucosa showed quite marked thickening due to fibrosis and showed a

scattering of eosinophiles. On the whole a slight intrinsic inflammatory reaction which is open to some doubt.

### SUMMARY

An attempt was made to definitely correlate undoubted mild inflammatory lesions of the appendix with a symptomatology of at least two weeks duration. The pathological reports, microscopic slides and clinical histories which had been collected during a period of two years, were the basis of the study. This material was taken from the various ward services of a general hospital and represented about 175 active public beds. Those appendices showing the mildest possible inflammatory reactions about which there could be no doubt were sought out. The clinical histories and findings of the patients from whom these appendices were removed were then investigated. While 37 appendices were found which met with the pathological requirements, there were only four instances where the symptoms had persisted more than two weeks. In these instances the symptoms had lasted respectively 3 weeks, 5 weeks, 4 months and 6 months. Case 3 had an associated gynecological condition which might have accounted for the symptoms, and in case 4 there is some doubt about the pathological lesion.

### CONCLUSIONS

The mildest inflammatory reactions of the appendix which are still within the realm of definite inflammation, are very rarely associated with symptoms of more than two weeks duration before the conditions obviously call for surgical intervention.

There is no typical symptom complex constituting clinical chronic appendicitis as defined in this paper. Both pain and indigestion may be present and neither has any distinctive features.

In so far as the clinical course indicates, there is no relation between duration and intensity in inflammatory reactions of the appendix. It would seem wise therefore to divorce the terms "subacute" and "chronic" from any time relationship in indicating types of appendicitis as viewed by the microscope.

In conclusion we should like to acknowledge the courtesy of the hospital, particularly the pathological department and the record room, in permitting us the use of their facilities.

### NINETY-NINE YEARS AGO\*

By JOSEPHINE COLEGROVE, NEW YORK, N. Y.

WE are inclined to think wistfully of the good old days, when a physician hung out his shingle and forthwith entered upon the practice of medicine. It seems ideally simple. But since reading the advice of Mrs. B.

to Mrs. L., in the year 1829, on the subject of choosing a family physician, I am a little dubious. It is rather terrifying to think of passing in review before her judicial eye. She is explicit and certain. Indeed, she shows no reluctance in set-

**Pathological Report** August 6, 1924 Tube shows Acute purulent Salpingitis Blood clots contain chorionic villi Ovary shows active corpus lutei Diagnosis Tubal Pregnancy and Acute Salpingitis Dr A Fraser, Pathologist

The patient made an uneventful recovery and left the hospital August 21, 1924, apparently none the worse for her experience

On June 9, 1926, I was again called in to see this case. She complained of severe pain in the left lower quadrant since the afternoon of June 5, 1926 Pain cramp-like in character was accompanied by spotty bleeding from vagina She was greatly prostrated and in a cold perspiration Last menstrual period April 21, 1926

On examination the abdomen was generally tender and definitely rigid in the left lower quadrant Uterus slightly enlarged and adherent to a tender mass in the left broad ligament Cul-de-sac painful but no free fluid Referred to hospital with a provisional diagnosis of Ectopic Gestation, but she did not decide to enter the hospital until two days later Condition seemed improved on admission Pain still present and cramp-like in nature but not so severe

**Examination** June 11, 1926 Abdomen Tenderness left lower quadrant but no rigidity Cervix patulous Fundus enlarged, about the size of a small grape fruit, 4 in x 6 in Small tender mass in left broad ligament HB 80% W B C 12 400 Polys 70% Temperature 103° Pulse 100 Respiration 18 Red Test

1st Hr	16%
2nd Hr	20%
Total	36%

The diagnosis was changed to Threatened Abortion with Salpingitis

June 13, 1926 Patient felt much better, pain moderately gone

June 17, 1926 Uterus had increased in size but still some pain in left broad ligament but very much less

June 19, 1926 Patient felt exceedingly well temperature normal, and decided to go home

The diagnosis of a Threatened Abortion with a flare up in left tube seemed to be fairly certain and inasmuch as the pain had apparently subsided she decided to go on to term under observation at home.

On June 27, 1926 I was again called to see her The pain recurred the following day and was accompanied with considerable bleeding The pain was sharp in character but chiefly on the left side, and required the administration of morphine to control it Cervix was patulous and fundus

corresponded in size to about end of the second month of pregnancy with a small tender mass in the left broad ligament She refused to go to the hospital and on July 1, 1926, she passed a foetus which was kept for my inspection, followed by secundines The foetus was intact in its sac measuring about 2½ in in diameter corresponding approximately to the seventh or eighth week

Everything went along fine until July 9, 1926, when the pain again recurred worse than ever and accompanied by moderate bleeding I advised immediate removal to hospital as mass in the left broad ligament had apparently increased in size and was extremely tender Her temperature was 105, Pulse 120, Respiration 22 She had just had a very severe chill

Admitted to St. Vincent's Hospital July 9, 1926, ice bags applied to abdomen The following morning her temperature was 103, pulse 110, respiration 20 HB 70% W B C 13,400 Polys 81 She was extremely ill and insisted that the character of the pain was the same as she had two years previously (Ectopic)

On examination the mass in the left broad ligament was very tender although the size apparently was not increased It was decided to operate upon her immediately

**Operation** July 10, 1926 On opening the abdomen a slight amount of free blood clots was found The left tube was immediately inspected and an unruptured tubal pregnancy was brought to view, with the fimbriated extremity acutely inflamed and full of blood clots (tubal abortion) The tube was removed, pelvis mopped dry and abdomen closed

**Pathological Report** Specimen consisted of an enlarged tube full of blood clots Section shows Chorionic villi and hemorrhage Diagnosis Ectopic Gestation Dr T Curphey, Pathologist

She made an uneventful recovery and left the hospital July 26, 1926 (16 days after operation), having been up and around the ward for four days feeling fine and happy

The chief point of interest in this case was the difficulty in differentiating between a threatened abortion complicated or caused by a flare up in the adnexa and an ectopic gestation in an inflamed tube The fact that the right tube had been removed in an operation two years previously did not facilitate a diagnosis of Coincident Pregnancy The passage of a well developed decidua membrane should not be confused with the ovum itself Had a tubal abortion taken place in this woman with a subsidence of the pain and little hemorrhage I probably never would have suspected the true condition

Mrs B is prompt in her response "Such I believe a nurse too frequently to be Let us now inquire what her qualifications ought to be

"A nurse should possess both physical and moral qualities to render services really useful to the sick She should be healthy, and not beyond the middle age of life, strong of body, and capable of enduring fatigue and loss of rest She should be easily roused from her sleep, watchful and active in all her habits, but at the same time quiet and gentle A bustling and talkative nurse is a great annoyance to an invalid She should be trustworthy, temperate, not a snufftaker, cleanly in her person, and orderly in her habits, and in her manners, rather taciturn, and willing to be guided by those above her She should be able to evince firmness in resisting the caprices of the patient She should also be able to read and write, for without these requirements she should never be permitted to administer medicines to the sick"

As a horrible warning, Mrs B then relates a "melancholy little anecdote" about a nurse who couldn't read or write, and who gave the patient an opium embrocation instead of a bark draught, with the result that "her family, who a moment previously had been indulging the joy her ex-

pected recovery had excited, were instantly bereft of a treasure, and plunged into the deep-seated grief"

Touching on a few further details, such as the undesirability of the habits of a glutton, and ill temper, and conceit, her final remarks are that, "Above all things, she should not be addicted to quackery, nor should she ever presume to prescribe medically"

Yet, after all, with the exception of some of the more lurid details, was it such bad advice? Echoes even seem to drift down to us now But, of course, things are different today The nurse has acquired an almost appalling efficiency—she even goes to college! As for the physician, a fashionable reputation still has its uses in the luring of patients, but at least the entire journal of his life need not be opened on demand But the patient, alas, seems sadly degenerated, a mere number on a case record This is the one thing Mrs B never thought of

\* Domestic Duties or Instructions to Young Married Ladies on the Management of Their Households and the Regulation of Their Conduct in the Various Relations and Duties of Married Life By Mrs William Parkes Third American, From the Third London Edition with Notes and Alterations Adapted to the American Reader New York Printed by J & J Harper 82 Cliff Street 1829

## COINCIDENT TUBAL AND UTERINE PREGNANCY

By AUGUST JAMES RAGGI, M D, NEW YORK, N Y

**A**LTHOUGH the occurrence of pregnancy in the uterus and Fallopian tube at the same time is mentioned briefly, if at all, in many of our text books on Gynecology, the condition I believe is frequent enough to warrant a more thorough study and yet rare enough to justify the report of a case

Tubal pregnancy occurs usually in the central portion of the tube, occasionally in the external and rarely in the internal or uterine end The union of the fecundated ovum and spermatozoon takes place at the abdominal end of the tube or before the ovum has escaped from the Graafian follicle The ovum is drawn into the tube by the wave-like motion of the cilia Any condition, such as inflammatory changes, which interferes with this course may cause its arrest in the tube

I shall not burden the reader with an extensive review of the literature on the subject, but instead I shall go over the history of this case in detail as it is very illuminating both from a diagnostic as well as a therapeutic point of view However F F Simpson\* as early as 1904 collected 113 cases including his own in the literature to that date

### Previous History

Mrs M C Age 26, Housewife, Married 11

years Three children Youngest child four years old Two miscarriages since last labor Cured after first miscarriage three years ago Menses regular for past year Menorrhagia ten or twelve days

Admitted to St Vincent's Hospital August 6, 1924, complaining of occasional attacks of severe pain in the right lower quadrant for two weeks On August 3, she was seized with a very sharp pain in the same region Vaginal bleeding, spotty in nature, but never very profuse, has accompanied patient's condition since the onset Vaginal discharge for four or five years

Examination Pale Severe anaemia of mucous membranes and conjunctiva HB 45% W B C 13,000 Polys 79% Urine showed Albumin 3 plus, Acetone 2 plus Temperature 102, Pulse 96, Respiration 28

Abdomen Large tender mass in the right lower quadrant Rigidity

Vaginal Uterus moderately enlarged and fixed to a large boggy tender mass in the right broad ligament Free fluid in cul-de-sac

Diagnosis 1 Ruptured Ectopic. 2 Ruptured Pyosalpinx

Operation Revealed an abdomen full of clots with a ruptured tube adherent to the right pelvis and intestines The right tube and ovary were removed

## PRESIDENTS' ANNUAL ADDRESSES

May and June are the months of annual meetings of the medical societies of many states and of the nation, and their official Journals are full of their proceedings. Their programs are developed along a standard plan which seems to fit the desires and inclinations of the members. The plans of the meetings fall under three heads, 1 those of the legislative bodies, the houses of delegates, in which questions of a civic and economic nature are considered, 2 those of the scientific sections, devoted to the practice of medicine in all its phases, and, 3 the commercial exhibits at which the physicians meet their friends who supply them with the physical means for practicing medicine.

The sessions of the houses of delegates are usually begun with presidential addresses, which shape and direct the entire proceedings. Presidential addresses are often looked upon as perfunctory affairs that are given under the compulsion of custom, but medical editors and reporters find them to be mines of news. Those of the meetings of recent years have been of increasing interest and value, culminating in their highest point in the 1927 meetings. The reason is probably that the presidents now do far more than those of a generation ago when office holding was largely honorary. Today he receives the greatest honor who has given the greatest service to his medical brethren and to the public.

There is a striking similarity between the presidential address of a physician and a carefully prepared sermon by a church pastor. Presidential addresses, like sermons, may be divided into three classes, 1 doctrinal, 2 inspirational, and, 3 educational.

Presidents have creeds, founded on the medical code of ethics, which is the medical golden rule. The words "I believe" occur frequently

in every presidents' address, and rightly so. Ministers of the Gospel have no monopoly of fundamental doctrines which are the compelling rules of their lives. Every president gives expression to his doctrinal creed spontaneously and naturally, and the reason is that physicians generally are actuated by lofty motives, which are worthy of the church.

Presidents naturally adopt an inspirational style of address, and "urge" the members to do their duty. They present the beauties of the straight and narrow path of ethical practice, and the destruction that awaits those who follow the broad way of self-advertising. There is also a growing tendency to urge physicians that their works shall give concrete expression to their creeds.

Presidents almost invariably make the latter half of their annual addresses of an educational nature, and review the activities of their terms of office. Those parts of their addresses are of special interest to readers of medical journals for they have a lasting historic value. The activities which presidents now discuss would have seemed strange a decade ago. Take, for example, the work of Committees on Public Relations. The practice of civic medicine was an unknown term a few years ago when state medicine was an actual threat employed to drive physicians into public health. Presidents now are pointing out the opportunities that await the medical profession to assert their leadership in all forms of public health as well as private practice.

Future historians will find the presidential addresses of the year 1927 to be mines of information which reflect accurately the aspirations and accomplishments of their medical constituents.

---

## SURVEYS BY THE NEW YORK ACADEMY OF MEDICINE

Surveying of governmental and community activities by citizen groups has become an important adjuvant in the functioning of our democratic society. There can be no enlightened public opinion without knowledge of facts ascertained by independent and competent citizens' bodies.

In the domain of health and hospital activities of New York City, the Academy of Medicine has acted as a fact-finding body through its Committee on Public Health Relations. Numerous surveys were made by this Committee which resulted in many improvements of the activities of the operating agencies, whether official or voluntary.

In 1912 through the good offices of this Committee of the Academy, the Associated Out Pa-

tient Clinics was established. It did yeoman's service in formulating for the first time in medical history the standards for Out Patient work.

In 1917 the Academy Committee made a survey of dispensaries which resulted in the establishment under the United Hospital Fund of a Committee for Dispensaries Development. The Rockefeller Foundation appropriated over half a million dollars toward the work of this Committee, which was recently completed.

In 1920-1921, the Public Health Relations Committee carried on a survey of hospitals, the report of which was published by G. P. Putnam's Sons under title of "The Hospital Situation in Greater New York."

In order that the vast store of information

## THE DISTRICT BRANCH MEETINGS

The experience of last year demonstrated that the District Branch meetings occupy a position that is unique and essential in the official organizations of the physicians of New York State, for they afford the principal opportunity for discussing the affairs of the County Society—the fundamental unit of medical organizations

The unusual success of the District Branches last fall was due largely to a careful preparation

of their programs through conferences of the officers of each District Branch with the officers of the constituent County Societies. These conferences are now being held in preparation for the coming District meetings, with the expectation that they will arouse a cumulative interest in the activities of the County Societies, the District Branches, and the State Society

JAMES E. SADLER

# MEDICAL PROGRESS

**Experience with the Scarlet Fever Antitoxin Serum.**—N Lunin of the Childrens' Hospital, Leningrad, mentions the persistency of the recent visitation of scarlet fever in Russia which has led to the manufacture of a pure antitoxin at the Institute for Experimental Medicine. A hundred patients were selected for its exhibition. It was assumed at the outset that septic cases and cases more than five days old were not amenable to serum treatment, and so far as possible these were excluded. Of the 100 cases six ended fatally, but from complications. In all cases the specific action of the serum was manifest, the symptoms due to the disease toxin subsiding, and the earlier the case the more striking the improvement. Serum sickness was very common, taking the form chiefly of urticaria, but no serious consequences were seen. The technique used in the United States for freeing the serum from unnecessary albumins was apparently used in the interest of prevention of serum sickness. The total number of cases treated in Leningrad in five hospitals is now over 700 and only severe cases have been thus treated. The mortality for this series has been a little over 10 per cent. The new serum differs but little from the old Moser serum but is more concentrated. If the first exhibition seems negative in result it is still possible to get positive results by persisting in its use. Serum sickness is chiefly to be expected in children with the exudative diathesis. It does not appear that any attempts at standardization of the serum have yet been made, and it is also apparent that attempts to free the serum from adventitious protein have not yet been completed, judging from the frequency of serum sickness.—*Deutsche medizinische Wochenschrift*, March 11, 1927

**Scarlet Fever Serum**—Prof J Husler, director of the Childrens' Division of the Munich City Hospital, gives his experience with the Dick serum which was introduced into Germany in 1925, as follows. He has used it in 34 cases of moderate to severe scarlet fever, but of this number only a minority were desperately ill. A specific action on the fever and exanthem was unmistakable and the altered mental state was striking. Some of the brighter children said they were well and wanted to get up. In other words the antitoxin actually produced a detoxicating effect. But to go to extremes by saying that the disease has become completely robbed of its terrors, the author says, is an exaggeration. The serum does not prevent some of the complications

and sequelæ. If it did possess this power we should feel obliged to give it to all patients, even those with minimal manifestations. This in turn would expose sensitive children to the danger of serum sickness, and between mild scarlatina and severe serum sickness Husler would prefer the former. Since 1912 the author has made use of convalescent serum in treating scarlet fever and the parallel between this and the American antitoxin is striking. The former, like the latter, exerts a marked antitoxic action and often has seemed to save life, but it does not prevent complications nor does the fact that it is a human product prevent it from causing anaphylaxis when given in large doses. Owing to the great difficulty in getting supplies of convalescent serum the antitoxin will replace it, and this can probably be improved further with time as regards standardization, etc. Of the prophylactic value of the American serum the author speaks encouragingly.—*Muencheener medizinische Wochenschrift*, April 29, 1927

**Cause of the Onset of Labor**—H Knauss of Graz refers to the now ancient theory that labor onset is determined in some way by the pituitary hormone, which was believed not only to stimulate the uterine muscle but also to activate the ovarian hormone and hence incidentally, by restoring the function of ovulation, to terminate gestation. The author has been at work along another line, viz., the maturity of the uterine muscle-cells which go through a certain cycle of development and which when at their physiological maximum, automatically determine the onset of labor. It may be shown decisively that the nervous supply of the uterus has nothing to do with the phenomenon. No one has ever succeeded in bringing on normal labor by the administration of any kind of drug until the muscle cells have reached a certain phase of development. However, we know that the growth of these uterine muscle cells is presided over by the ovarian hormone, for in all animals (with the possible exception of apes) double ovariectomy during pregnancy is followed by absorption or expulsion of the fetus. The hormone in question undoubtedly comes, Knauss holds, from the corpus luteum. The pituitary hormone appears to be able to intensify normal contractions of the uterus into labor pains, but there is no absolute evidence that it normally determines labor. The author's studies on rabbits appear to show that by the three-hundred and first or three-hundred and second day of gestation the uterine muscle cells begin to develop

collected during the survey, concerning all phases of hospital work should not become only of historical value, the Committee suggested to the United Hospital Fund that a special Bureau be organized to keep alive and up-to-date, all the facts pertaining to hospital organization and hospital performance. Accordingly, a Bureau was established under the name of the Hospital Information and Service Bureau, which has been operating on an increasing scale since 1922. From its inception the Bureau has been very closely linked with the work of the Academy of Medicine by having as its director the Executive Secretary of the Public Health Relations Committee.

In the June issue of the *Bulletin* of the New York Academy of Medicine there appears a very interesting address by the President of the Academy, Dr S W Lambert, in which he dwells on certain of the problems of the United Hospital Fund in relation to the medical profession.

In it he emphasizes the close bond which exists between the Fund and the Academy and the need for a closer understanding between the board of trustees of hospitals and the medical boards. Incidentally he points out the need for a better appreciation by laymen of the services rendered by physicians to the hospitals. The contribution of medical men should absolve them from financial solicitations toward hospital maintenance. Pointing out the increasing amount of costs in hospital care, which are in part due to the legitimate demands of the medical staffs for proper diagnostic and therapeutic equipment, he very wisely concludes by the statement "Although all this is a legitimate expense, it must be watched to avoid extravagance."

Hospital economics is a subject which is justly receiving a great deal of thought on the part of those concerned with community problems.

### MINUTES OF THE ANNUAL MEETING

An account of the proceedings of the annual meeting of the Medical Society of the State of New York is contained in three issues of this JOURNAL. The annual reports of the officers and committees are found in the JOURNAL of May first.

A descriptive account of the several sessions is found in the June first issue.

The official minutes of the House of Delegates are printed on page 670 of this issue.

The papers read before the scientific sections will be published throughout the year, and some will be found in each issue.

A special number in the early Fall will be devoted to the cancer exhibit.

### LOOKING BACKWARD

#### This Journal Twenty Years Ago

*Pre-clinical Medicine*—The manuals on Periodic Health Examinations emphasize the importance of the pre-clinical signs of disease, meaning those which occur during the early stages before the patient is disabled with his illness. The importance of these signs were well recognized twenty years ago, as is shown by the June, 1907, issue of this Journal, whose leading article is on Danger Signals from the Skin, by L Duncan Bulkley, M.D., New York. The author discusses the following nineteen conditions in a manner that is entirely up-to-date at the present time.

1 Syphilis, with special reference to blindness and brain tumors

2 Eczema in a general nervous and physical breakdown, especially in errors of diet and in eyestrain

3 Acne, especially in digestive disturbances and in menstrual disorders

4 Psoriasis, often called "The eruption of health," but often pointing to kidney trouble

5 Chronic Urticaria, clearly pointing to intestinal disorders

6 Erythema multiforme, in auto-intoxications

7 Pruritus in lowered nerve vitality (whatever that may be)

8 Xanthoma Diabeticorum

9 Boils and carbuncles, indicating "Lowered Vitality"

10 Dermatitis maligna, or Paget's disease of the breast

11 Acanthosis nigricans with multiple capillary Angiomata—if on the abdomen, points to intestinal cancer

12 Lupus vulgaris

13 Purpura rheumatica

14 Petchial and erythematous rashes in chronic infections

15 Purpureal lesions in spotted fever

16 Rose spots in typhoid

17 Pigmentary alterations, as in Addison's disease

18 Sweating and flushing of the skin, (now recognized as evidences of neuro-circulatory asthenia)

19 Dermatitis medico-mentosa

by far more common is the atebrole, or apyretic, which is present in more than one-half of all cases and occurs in the classical type of renal tuberculosis. In this type the apyrexia is total from the author's viewpoint but that does not mean that it does not rise above our classical  $98.6^{\circ}\text{F}$ , for according to him "normal is anywhere between  $97.7^{\circ}\text{F}$  and  $99.5^{\circ}\text{F}$ ". In the last 121 of the author's cases no less than 71 were "afebrile". The second type is termed by the author the acute febrile and is relatively rare, occurring in some ten per cent only. Even by the evening of the day of operation and usually within the first 24 hours the temperature may go as high as  $104^{\circ}$  and even  $105^{\circ}$  and upwards ( $105.8^{\circ}$ ). This type is encountered in subjects with old tuberculous foci elsewhere—bones, joints, lymph nodes. The prognosis is favorable and defervescence soon sets in. The collateral lesions mentioned are presumably cicatrized and may have shown no activity for very many years. The third and last type is a continuous oscillating fever and is encountered in about one fourth of all cases. There are often collateral lesions as in the second type but these are apparently still active or at least not permanently healed. The first rise of temperature is seen the day after operation and the fever is of moderate intensity, appearing late in the day, the patient being afebrile in the morning. The type is that of hectic fever, so much so that the author terms it "surgical consumption". Convalescence is tedious and the patient may be kept in the hospital for months on account of both the general state and the refusal of the wound to close permanently.—*Le Bulletin Médical*, 1927, vi, No. 16

**Some Varieties of Headache**—In an address before the Stafford Division of the British Medical Association, published in the *British Medical Journal*, April 2, 1927, 3456 Lord Dawson discusses the pathogenesis of headache. Among the etiological factors, which vary in different individuals and even in the same individual at different periods of life, he finds heredity, anxieties, fears, repressions and other psychic conditions, fatigue and exhaustion, gastroenteric disorders (proneness to fatigue, leading to failure of motility, and perhaps secretion, the brain and solar plexus being in error), and hepatic insufficiency. In some cases several of these factors may contribute, whereas in others one will dominate. Eyestrain, tobacco, and alcohol may be exciting factors. In cases in which psychic causes are responsible, the best treatment is to show the patient the nature of the problem. As regards the alimentary tract, once-cooked foods, the avoidance of fats, and in some cases restriction of sugars are important. Persons in whom gastroenteric disturbances are induced by fatigue should be careful to be warm when eating and to partake of light food when tired. When the

headache is mainly due to hepatic insufficiency the routine administration of calomel and a saline is beneficial, but for many, if not most, headache-subjects strong aperients are harmful. Castor oil in doses of 1 to 3 drachms once or even twice a week helps many, and others can take the lighter aperients like cascara or senna. Any palliative must be taken at the outset. Salicylate and bromide and sal volatile suit many. Phenacetin is invaluable and amidopyrine helps a few.

For those prone to acidosis sodium bicarbonate is indicated. Luminal is in some cases helpful, but its effects must be watched, as it is not well borne by some patients. Skilled massage of the head and neck, and manipulation which includes gentle traction of the head from the trunk, bring great relief to some persons. Headache illustrates a problem which will increasingly occupy the attention of the medical profession—that of the keeping of man in the path of "physiological righteousness".

**Relief of Migraine by the Administration of Concentrated Salts**—H. C. Rook (*The Lancet*, April 2, 1927, ccxii, 14) observes that the old idea that migraine was of hepatic origin has gradually given away to the modern theory of fatigue, eyestrain, or some endocrine defect. It appears that a combination of the old and modern theories is the correct view, and that migraine, at least in a percentage of cases, is caused by hepatic toxins, which in predisposed subjects may be produced by nervous overaction or inhibition. On the basis of this theory, Rook prescribes 2 to 4 ounces of 50 per cent solution of magnesium sulphate one hour before rising, and following this the patient is instructed to lie semiprone on the right side. At the end of an hour a large tumblerful of hot water or hot weak tea is taken. This is most important, since if the salts are not evacuated within two or three hours, a feeling of intense depression is produced which may result in an attack. The day or half-day previous to taking the salts is a starvation period. Each patient must be treated with regard to individual peculiarities: usually the treatment should not be carried out oftener than once a week, and with some persons it is sufficient to give the salts once a fortnight. Certain articles of diet must be strictly limited. These are fats of all sorts, and in certain cases eggs, also chocolate, cocoa, coffee and alcohol, especially spirits. Regularity of habit should be urged and as far as possible freedom from worry and fatigue.

**Monocytic Angina**—According to Haken of Berlin this affection was first isolated in 1922 by Schultz and Baader and owes its name to the peculiar blood picture in which the large mononuclears of Ehrlich show a marked in-

spontaneous contractile movements which suffice to set labor in motion. A day or so before term an infinitesimal quantity of pituitrin suffices to bring on labor promptly, but for the day before that a far larger dose is required and so on, until the time when no amount of the drug will exert this action—*Muenchener medizinische Wochenschrift*, March 4, 1927

**Clinical Causes and Diagnostic and Prognostic Significance of Jaundice**—In presenting a summary of the present status of our knowledge of jaundice, David Reisman (*American Journal of the Medical Sciences*, May, 1927, clxxiii, 662) quotes from the literature to show that no definite proof has been brought that bile is chiefly formed outside of the liver, in the so-called reticulo-endothelial system, or that the liver is merely an excretory organ for bile made elsewhere. He is inclined to believe on clinical grounds, that bile can be formed extrahepatically. The classification of the causes of jaundice into mechanic and dynamic is, in the main, satisfactory, though perhaps a little too rigid. After reviewing the causes of obstructive jaundice and of toxic and infectious jaundice, Reisman reports three cases of epidemic jaundice, in the last of which bile was detected in the urine before the color of the eyeballs attracted attention. Cases of this kind are in the beginning usually called influenza—often abdominal influenza—during the period of apparently causeless fever, nausea, and vomiting. The subsequently discovered jaundice is considered a sequel or a complication. The whole process, Reisman believes, is a unitary disease due to the same obscure transmissible infection which with modern technique should not long elude discovery. Epidemic jaundice seems to bear a relation to acute yellow atrophy or acute degenerative hepatitis. This is illustrated by the case of a physician who fell ill a few weeks after attending 18 or 20 cases of epidemic jaundice and died of acute degenerative hepatitis. One cannot escape the belief that an infection was at work and that the doctor had received such an intensive dose of the poison that he developed what is comparable to an acute yellow atrophy of the liver. In discussing congenital and acquired jaundice it is shown that many features are common to both types and that the differences are scarcely fundamental. In determining the cause of jaundice, it is well to remember that painful jaundice is usually due to mechanical causes, especially to stone, cholecystitis, or cholangitis. If the jaundice is painless, the possibilities are many, with clay-colored stools and choluria, the suspicion falls on the pancreas or some nearby structure. A large gall-bladder is suggestive of disease of the pancreas. Glycosuria also favors the diagnosis of pancreatic disease. A variable icterus index speaks in favor of stone, a constant or increasing figure is most common in extraductal or

noncalculous obstruction. Functional liver tests at present give information as to the state of the liver rather than as to the causes of jaundice. In hemolytic jaundice, barring the graver anemias and hemolytic poisons, the prognosis is favorable. Cure is often achieved by splenectomy. No form of obstructive jaundice should ever be taken lightly. In the presence of jaundice the surgeon should limit his interference to the essential minimum.

**Conjunctival Icterus as a Sign of Appendicitis**—Dr C P Caplesco, of Bucharest makes a second contribution on this subject six years after the first. Up to that time he had recorded fifty cases of diagnosis of latent appendicitis in which conjunctival icterus was present and which influenced him in arriving at the diagnosis. All of these patients were subjected to appendectomy and all of the appendices showed evidence of disease—hyperemia, increase in volume, and content of bloody matter, feces, or calculi, with the mucosa showing black points and ulcers of various sizes, and the submucosa fibrotic or sclerotic. The icterus was attributed by the author to a toxin elaborated by the diseased appendix. During the intervening six years he has operated on 750 patients with some form of appendicitis—acute, chronic, or latent—and has found his symptom present in every case. Adding the original 50 cases the total of positive finds is now an even 800. He is about ready to set up the dictum that there is no appendicitis without conjunctival icterus. The converse of course is not true—that is, every case of conjunctival icterus does not mean appendicitis, but it would be of much interest to learn how large a proportion of the icterus cases do suffer from these lesions and also what is the frequency of this discoloration. There is a minimal degree of icterus which is not reckoned as pathological. Of one material of 254 school girls 11 to 18 years of age, 99 showed icterus to an abnormal degree. In 100 male students from 19 to 26 years of age no less than 81 showed icterus. The author does not venture an opinion as to the percentage of these students who actually suffered from latent appendicitis, but he thinks the figures show that at the preferred age of appendicitis icterus of the conjunctiva is extremely common, and he evidently believes that it is due to some abnormality of the appendix in the majority of these cases—*Bulletin de l'Académie de Médecine*, Paris, April 19, 1927.

**Three Temperature Types After Nephrectomy for Tuberculosis**—F Cathelin of the Paris Urological Hospital describes three types of temperature following nephrectomy in the tuberculosis of which the first and

# LEGAL

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York.

## THE ADDRESS OF THE PRESIDENT OF THE UNITED STATES

At the recent annual meeting of the American Medical Association in the Arcadia Auditorium at Washington, President Coolidge delivered a noteworthy address. A large gathering of physicians from every part of the country greeted the President and listened with interest and just pride while he extolled the aims and the principles of the medical profession.

There is all too little recognition and appreciation on the part of the lay public of the Doctor and the purposes for which he spends his life. Perhaps from this fine, cogent and sincere address delivered by a man who justly has acquired and increasingly holds the respect and confidence of everyone, irrespective of party affiliation, may come a clearer and a juster understanding on the part of the lay public of what it is for which the medical profession has striven and is endeavoring to accomplish.

"Those who have witnessed the general paralysis which prevails when even a moderate epidemic breaks out," the President declared, "cannot help but realize that one of the most important factors of our everyday existence is the public health, which has come to be dependent upon sanitation and the medical profession. We are constantly in receipt of the beneficial activities of these efforts in the disposition of waste, the water we drink, the food we eat, and even in the air we breathe." \* \* \* In its main aspects it is preventive, but in a very large field it is remedial. Without this service our large centers of population would be overwhelmed and dissipated almost in a day and the modern organization of society would be altogether destroyed. The debt which we owe to the science of medicine is simply beyond computation or comprehension."

To the critics and the assailants of the medical profession these words, coming as they did from the Chief Executive of the nation, should have the weight and respect and the influence to which both by their truth and the authority which uttered them they are entitled.

How keenly conscious of the true nature of science and of the efforts which it is every hour putting forth in the interests of mankind the President was appeared when he continued "But great effort is being put out

all around us and a constant advancement of knowledge is in progress. This has been especially true in the science of medicine. Many of the diseases which laid a heavy toll on life have been entirely eradicated and many others have been greatly circumscribed. The average length of life has been much increased."

And still further "If there is any one thing which the progress of science has taught us, it is the necessity of an open mind. Without this attitude very little advance could be made. Truth must always be able to demonstrate itself. But when it has been demonstrated, in whatsoever direction it may lead, it ought to be followed. The remarkable ability of America to adopt this policy has been one of the leading factors in its rise to power. When a principle has been demonstrated, the American people have not hesitated to adopt it and put it into practice. Being free from the unwarranted impediments of custom and caste, we have been able to accept whole-heartedly the results of research and investigation and the benefits of discovery and invention."

These truths, could they once become generally understood and recognized, would put an end once and for all time to charlatanism and quackery. There is no more open-minded body of men in any field of endeavor than the members of the medical profession. They do not oppose the cults and the quacks because of jealousy or from any other improper motive. All that they say is that they will refuse to endorse and approve so-called medicines and cures whose real power to achieve that which it is claimed for them has not been demonstrated. They refuse to subscribe to claims incapable of demonstration. "Truth," said the President, "must always be able to demonstrate itself." When any assertion is capable of demonstration, there is no one more ready to embrace it than the Doctor, because every scientific man recognizes it as a fundamental tenet of his faith and that, as the President declared, for the "progress of science" there is "the necessity of an open mind."

With a clear appreciation of all that the medical profession has done, the President went on, "There is no finer page in the history of civilization than that which records the

crease Thus far, owing to its mild course, monocytic angina has attracted but little attention, but the author in his present paper relates three fatal cases with autopsy in all The patients were children from 4 to 8 years of age The duration of the disease in these patients was from 3 to 15 days Clinically the disease was of the septic sore throat type, a necrotizing angina with a very thick and discolored deposit The flora obtained by cultivation showed no type In one were found diphtheria bacilli and later the Vincent symbiosis, in the second only staphylococci, and in the third diphtheria bacilli with later a few hemolytic streptococci Two of the patients then seem to have had an initial diphtheria, at least from the bacteriological standpoint, but the bacilli disappeared from the throat at an early period and the subsequent course of the disease did not resemble diphtheria at all The first child received a single injection of antitoxin at an early period but no favorable reaction was seen In all three children the spleen was enlarged, but only two showed enlargement of the cervical regional lymph-nodes The increase of monocytes in the blood was from about 25 to 32 per cent over normal Etiologically the disease is a puzzle both from the absence of a typical causal organism and from the lack of a contagious or infectious element The author does not mention in this connection the septic sore throat which at times has been associated with an infected milk supply, and perhaps he has never heard of it—*Deutsche medizinische Wochenschrift*, April 1, 1927

**Circum-injection of Autogenous Blood in the Treatment of Carbuncles**—Louis Carp (*Archives of Surgery*, April, 1927, xiv, 4) reports 12 cases of definite progressive carbuncles in nondiabetic patients treated solely by the circum-injection of autogenous blood, without the utilization of other accessory measures, such as incision, local heat, or narcotics After the injections the infection did not spread, except in one case, there was quick relief from pain and constitutional symptoms, no reaction was observed after injection Most of the slough liquefied The injected blood seemed to remain in the tissues, with gradual modification, for from several days to two weeks, as evidenced by induration or ecchymosis, or both A violaceous color around the carbuncle appeared after an average interval of six days All the patients showed a minimal scar at the time of discharge from the hospital There was no recurrence of the infection locally Carp believes that the time for cure was probably shorter than it would have been by surgical procedure, although it was impossible to have a series of exactly the same carbuncles with surgical therapy as a control The technique

consisted in preparing the infected area in the usual manner, administering an anesthetic, preferably gas and oxygen or ethyl chloride inhalation, withdrawing blood from the median basilic vein into a 20 c.c. syringe, and immediately injecting it just beyond the margin of induration of the carbuncle Intracutaneous or subcutaneous injection is begun under considerable pressure, but the needle is pushed perpendicularly deeper and deeper until little pressure is required to force in the blood From three to six punctures are made, a sterile needle being used for each injection The author discusses at length the possible mechanism of the curative phenomena

**Some Clinical Aspects of Primary Carcinoma of the Pancreas**—B. M. Fried calls attention to the difficulties in the diagnosis of primary carcinoma of the pancreas, and asserts that it is often impossible to differentiate between a pancreatic and an hepatic tumor, or between a tumor and an inflammatory condition of the pancreas The complexity of diagnosis is largely due to the topography of the pancreas In the early stages primary carcinoma of the pancreas, like carcinoma elsewhere in the body, runs a silent course The first symptoms depend upon the part of the organ primarily involved In cancer of the head of the pancreas the dominating factor is pressure upon the ducts resulting in icterus and enlargement of the gall-bladder, in cancer of the body the irritation, or possibly the involvement by the new growth, of the solar plexus, causing excruciating epigastric pain, is the outstanding symptom Jaundice is lacking Severe pain may also be present in cancer of the head or tail of the pancreas when, due a protracted course, the new growth from these parts of the organ has probably reached the body and has invaded the solar plexus In primary carcinoma of the body of the pancreas at the onset of the disease the pain is usually confined to the epigastrium, and comes on in paroxysmal attacks at various intervals Later the pain is more constant, sharp, not related to meals, frequently resembles the gastric crises of tabes, and radiates to the spine or the thorax There is often a diarrhea accompanied by colicky pain and tenderness A case is reported in which there was a history of excruciating epigastric pain of one year's duration in a man of 70 Necropsy revealed a tumor which to all appearances originally started in the caudal part of the pancreas and progressed toward the body Here, as in primary cancer of the head of the pancreas, the outstanding symptoms were not due to involvement of the organ, but were "borrowed," so to say, from its topography—*Boston Medical and Surgical Journal*, April 21, 1927, cxvi, 16

ether and lysol solution. The injection was then made in the anterior aspect of the thigh about a third of the distance from the knee. The patient seemed to be nervous and had not fully made up her mind whether or not she wanted the injection. The patient was accompanied by her mother who had told the physician to proceed with the giving of the injection, telling the patient that the same would not hurt. Just as the physician was about to administer the hypodermic injection the patient grabbed his hand. He cautioned her not to move and to keep quiet. He then inserted the needle in the leg and when the same was partially inserted the patient again grabbed the physician's hand, causing the physician to press heavily upon the needle so that the same broke at the hilt. The physician immediately notified both the patient and her mother that owing to the movement of the patient and the grabbing by her of the doctor's hand, the needle had broken and that part of it was in the patient's leg. He then endeavored with his fingers and with forceps to remove the needle, but was not able to locate the same. The physician further advised both the patient and her mother that the needle was sterile and that if it were permitted to remain in the leg it would not cause any injury, that she should return home and that he would make arrangements for the attempted extraction of the needle by means of an electro magnet.

During the evening of the day when the hypodermic injection was administered and the needle had broken, the patient's husband telephoned the physician, stating that the patient's leg was swollen and that she was suffering intense pain. The physician then called upon the patient at her home, at which time she complained of pain in the leg and the physician prescribed cold compresses of boric acid solution. Upon examination he found no swelling of the leg, no irritation or apparent infection. On the morning of the following day he again called upon the patient at her home, examined her leg, found no swelling, irritation or infection and advised that he would arrange for the attempted extraction by an electro magnet. The physician located an electro magnet at a physicians' supply house, and arrangements were made for the use of the magnet on the following morning. The physician took the patient to the supply house and applied the electro magnet to the patient's leg, but was not successful by this means of extracting the needle. Thereafter, an X-ray was taken which showed the presence of the needle in the leg, but not

imbedded in the bone. After examination of the X-ray the physician advised the patient that surgical interference was not necessary at that time, that the needle would not migrate and would not cause any injury, and advised that it be left alone for the time being. He further advised against surgical interference during the pregnant condition of the patient. Several days later he again called at the patient's home, examined the leg and found no swelling, irritation or infection. The patient, however, was limping while she walked. A few days thereafter the husband of the patient called at the physician's office and advised that he was taking his wife to a hospital. No further treatment was rendered by the physician nor was the patient again seen by this physician.

Actions of alleged malpractice by the patient and her husband were instituted against the physician. In the complaints it was alleged that the defendant as a physician had been engaged to administer to the patient for the pains from which she was suffering shortly prior to the birth of a child, and that the defendant physician was careless and negligent in and about the care of the patient and particularly about the care of her right leg, where he had inserted a hypodermic needle in such a negligent and careless manner as to cause the needle to break off in the patient's leg, that the needle had entered the bone where it has remained ever since and that by reason of the carelessness of the defendant in the hypodermic administration, the patient was caused great pain and anguish and her leg to become swollen and inflamed and her general health to become greatly impaired, for which she sought to recover money damages.

The husband in his action sought to recover damages for medical expenses claimed to have been incurred in the further treatment of his wife and for the loss of her services.

On behalf of the plaintiff a motion was made for a preference upon the trial calendar on the ground of the impecunious condition of the plaintiff and need for money in order to procure further medical treatment alleged to have been rendered necessary by reason of the defendant's negligence. The preference for a trial was granted. When the action appeared on the calendar for trial a dismissal was had of the complaint because of the non-appearance in behalf of the plaintiffs and judgment dismissing the complaints was entered in favor of the defendant.

advance in medical science. The heroism of those who have worked with deadly germs and permitted themselves to be inoculated with disease to the end that countless thousands might be saved, was less spectacular, but no less far-reaching than that on the battlefield or of an isolated rescue from a burning building or a sinking ship."

Citing William Osler as his authority the President called attention to the fact that the average working life of English speaking men had been doubled within three centuries, and that most of that gain had been made within the last fifty years.

"The development of preventive medicine," the President continued, "has been one of the outstanding features of that period. Whereas in the old days the doctor healed, if he could, those who had become afflicted, the greatest stress today is laid upon keeping the body sound and efficient. Proper methods of living are taught and suitable diets are prescribed. Hygienic conditions for the home, the workshop and the factory have been adopted. Periodic physical examinations are urged in order that disease may be turned back before it has become seriously developed."

The increasing capacity of physicians to work together for the accomplishment of the fundamental aims of their profession, and their willingness to adopt and apply any knowledge once it has borne the test of scientific scrutiny, were duly noted by the President.

"Cooperation and tolerance," he said, "which have been developed so widely in industrial and social relations," are now found in a marked degree in the medical profession. The work being done by the American Medical Association is a striking illustration of this. In years gone by physicians were apt to be suspicious and intolerant of other schools and of other methods of treatment. There has been a great change. The modern broad-minded physician is willing to use or to recommend whatever methods seem best suited to the case in hand. Furthermore, he is the

strongest advocate of prevention. He it is who is taking the lead in the development of everything which promises to promote health and to reduce sickness to the minimum, even though its tendencies are to diminish the practice upon which he relies for his income."

The truly humanitarian and unselfish motives that inspire the medical profession were fittingly acknowledged by the President of the United States when he declared "Our larger cities support free dispensaries, our hospitals have provision for free service, and of all the professions, with the possible exception of the ministry, our physicians give most unsparingly of their time and their skill for the alleviation of human suffering."

Casting his eye over the horoscope of the future, Mr. Coolidge closed his address with these words, constituting at one and the same time both a prophecy and a tribute to the healing art and all those who follow it. "What part the physician will play in the further advancement of the well-being of the world," he said, "is an interesting speculation. It is a well-known proverb that 'Cleanliness is next to godliness.' No one can doubt that if humanity could be brought to a state of physical well-being, many of our social problems would disappear. If we could effectively rid our systems of poison, not only would our bodily vigor be strengthened, but our vision would be clearer, our judgment more accurate and our moral power increased. We should come to a more perfect appreciation of the truth. It is to your profession in its broadest sense, untrammelled by the contentions of different schools, that the world may look for large contributions towards its regeneration, physically, mentally and spiritually, when not force but reason will hold universal sway. As human beings gain in individual perfection, so the world will gain in social perfection, and we may hope to come into an era of right living and right thinking, of good will, and of peace, in accordance with the teachings of the Great Physician."

---

### BROKEN NEEDLE IN HYPODERMIC INJECTION

A woman about 24 years of age called upon the physician at his office for the purpose of arranging for her care during her expected confinement. At this time she was about eight months pregnant. She stated to the physician that she was still troubled with nausea and vomiting. The physician advised the injection of a lutein preparation made from the corpus luteum of the ovary which he stated

had proved successful in previous cases in controlling nausea during pregnancy. For the purpose of administering the medication a hypodermic needle was prepared, the physician taking a new needle, about three-quarters of an inch in length, which had not been previously used. After sterilizing the needle the site of injection on the patient's leg was likewise sterilized with an antiseptic soap, alcohol,

embellishment and known to contain dangerous chemicals, like lead, arsenic, barium, wood alcohol, various amines, particularly para phenylene diamin, and various solvents, coal tar derivatives, benzol, etc.,

And, WHEREAS, Seldom, if ever, is the public warned by label, device, or other mark of the presence of such dangerous chemical;

And, WHEREAS, Drugs and chemicals used for cosmetics, or personal adornment, are not included in the National Pure Food and Drug Act,

*Be It Therefore Resolved* 1 That it is the sense of this House that this use of dangerous chemicals is a menace to the welfare of the public and against the best interests of the public health,

2 That it is recommended that all pharmaceutical manufacturers and proprietary remedy producers be publicly advised of this dangerous practice,

3 That it is the recommendation of this body that all packages containing material, alone or in combination, intended for cosmetic use, be properly labelled when such contains a drug or chemical which when improperly or frequently used may cause irritation of the skin or illness,

4 That any remedy for use in ornamentation containing an appreciable amount of any drug or chemical contained in the list of known dangerous chemicals, be required to bear the usual poison label and a red label be used as is generally done in pharmacies when handling materials for external use,

5 That the State Society approves of efforts to require public regulation of all dangerous chemicals used in the embellishment of the human being, and that such preparations be made subject to the same rules and laws as govern drugs in the State Pharmacy Act,

6 That the Delegates to the American Medical Association from this body, be herewith instructed to present resolutions to the House of Delegates of that body, memorializing Congress to approve of an Act requiring cosmetics to be subject to the same rules and regulations in interstate traffic and commerce as are required of drugs generally,

7 That in order to prevent deceit and fraud in these sales or use of cosmetics, any amendment considered, regarding publicity or information, shall be fair, truthful, and no claim to be made which is not within the accepted scientific knowledge of any article or ingredient or combination of such materials, not only in and about the package, but wherever such claims are made,

8. That any preparation sold for self-use, without a prescription (Rx), and containing an appreciable quantity of a known poison shall be labelled with the word and insignia usually applied to such materials and the nature of the drug, together with the approved antidote with suggested first aid be clearly printed on each such package.

*The Vice Speaker* This resolution will be referred to Reference Committee A, on New Business (Report in Sec. 23)

#### 7 KINGS COUNTY AMENDMENTS TO THE CONSTITUTION AND BY-LAWS

*Dr Goodrich Kings* Mr Speaker, with a cordial earnest desire to contribute to the safety, the soundness, the fraternalism and the greatest possible progress of the Medical Society of the State of New York and with the definite aim of perfecting the development of mutual confidence and co-operative efficiency which would result from a truly representative government, the delegation from Kings County presents the following amendments to the Constitution and By-Laws of the Medical Society of the State of New York.

The Constitution now reads as follows

Article IV The Council shall be composed of (a) officers of the Society (b) Chairmen of the Standing Committees (c) the Editor-in-Chief, (d) the retiring

President for a term of one year after his term of office has expired"

This is to be amended to read

"The Council shall be composed of the President, the Secretary, the President-Elect, the Treasurer, and the President and Secretary of each of the District Branches"

Article V now reads as follows

"The officers of the Society shall be a President, a President-Elect, two Vice-Presidents, a Speaker, a Vice-Speaker of the House of Delegates, a Secretary, an Assistant Secretary, a Treasurer, an Assistant Treasurer, five Trustees, and one Councillor from each District Branch, who shall be the President thereof. He shall be elected by the District Branch in which he resides for a term of two years. The officers, except the Councillors, shall be elected for one year or until their successors have been duly chosen. They shall take office at the termination of the annual meeting."

This to be amended to read

"The officers of the Society shall be a President, a President-Elect, two Vice-Presidents, a Secretary, an Assistant Secretary, a Treasurer, an Assistant Treasurer, a Speaker, a Vice-Speaker, five Trustees, and two Councillors from each District Branch, who shall be the President and Secretary thereof. They shall be elected by the District Branch in which they reside, for a term of two years. The officers, except the Councillors, shall be elected for one year or until their successors have been duly chosen. They shall take office at the termination of the annual meeting"

Amend the By-Laws

Section 26 to be repealed and amended to read

"The Executive Committee of the Council shall be constituted as follows. The President, the Secretary, the Treasurer, and four of the eight Presidents of the District Branches, those from 1, 3, 5, 7, serving for one year and those from District Branches 2, 4, 6, 8, the next. The Executive Committee shall, when elected, organize immediately and elect a Chairman, a Vice-Chairman and a Secretary. The Executive Committee shall hold regular meetings at times and in places that shall be fixed by the Chairman and at other times subject to the call of the Chairman, and any two members of the Executive Committee may require the Chairman thereof to call a meeting for such time and place as shall be designated by them in writing, of which the members shall have at least three days' notice. Four members shall constitute a quorum. It shall prepare a budget to be acted upon by the Board of Trustees"

Section 38 to be repealed and amended to read

"The Speaker shall preside at all meetings of the House of Delegates and shall perform such other duties as parliamentary usage may require."

Section 62 to be repealed and amended to read

"The President shall report to the Council the committees that he shall deem expedient for the purposes of the meeting of the House of Delegates and the members of these committees shall be elected by the Council at the meeting of that body in February, preceding the meeting of the House of Delegates"

Section 20 of the By-Laws to be repealed and amended to read

"It shall meet once during the months of October, December, February and April of each year, the time and place to be selected by the President, and it shall meet at other times upon the request in writing of five members of the Council upon the call of the President."

I submit these, sir

*The Vice-Speaker* All suggested amendments to the Constitution and By-Laws must lie over for one year

#### 8 WESTCHESTER COUNTY RESOLUTIONS ON STATE BOARDS OF NURSING ADMINISTRATION

*Dr Stanuax, Westchester* The Medical Society of the County of Westchester calls attention to a situation

# HOUSE OF DELEGATES

## HOUSE OF DELEGATES

The Annual Meeting of the House of Delegates of the Medical Society of the State of New York was held at the Niagara Hotel, Niagara Falls, on Monday afternoon, May 9th, 1927. Speaker, Dr E. Eliot Harris, Vice Speaker, Dr Harry R. Trick, Secretary, Dr Daniel S. Dougherty.

The Speaker announced that the secretary would call the roll by counties for the purpose of determining the presence of recognized delegates. A quorum being present, the Speaker declared the House organized for business.

### 1 REPORT OF THE COMMITTEE ON CREDENTIALS

*The Speaker* The first order of business is the report of the Committee on Credentials, Dr Dougherty.

*The Secretary* Mr Speaker and Gentlemen the Committee on Credentials has the pleasure of reporting that there is no duty for it to perform, as there are no disputed delegations.

### 2 IN MEMORIAM OF DRS CAMPBELL AND JONES

*The Vice Speaker* The Speaker has asked me to read the following communication.

Since the last meeting of the House of Delegates death has taken two ex-Presidents who were life members of this House, our beloved Dr William Francis Campbell and Dr Owen Elon Jones. Out of respect for our deceased life members I shall ask the House to rise and remain standing in silence for two minutes.

The House thereupon rose and remained silent for two minutes in respect to the memory of Dr William Francis Campbell and Dr Owen Elon Jones (Sec. 56).

### 3 APPROVAL OF MINUTES

*The Vice Speaker* The next order of business is the reading of the minutes of the previous meeting. They have been published. Are there any corrections or additions? If there are none, they will stand approved as printed, and it is so ordered.

### 4 PRESIDENT'S ADDRESS

The next order of business is the address of the President. (Reference Committee's report in Sec 45)

### 5 REFERENCE COMMITTEES

*Dr H S Patterson, New York* It has been customary heretofore that the addresses be referred to the various reference committees. I suggest the appointment of a reference committee on this address.

*The Vice Speaker* That does not require a second. Mr Secretary, you will kindly read the reference committees appointed by the Speaker.

The Secretary read the appointments as follows.

Reference Committee on Credentials—Daniel S. Dougherty, New York, Chairman, Morris Maslon, Warren, Le Roy Becker, Schoharie, George Mord, Richmond, Harvey W. Humphrey, Lewis.

Reference Committee on President's Address—Horace M. Hicks, Montgomery, Chairman, Walter T. Dannreuther, New York, Thomas C. Chalmers, Queens, James H. Flynn, Rensselaer, Norman L. Hawkins, Jefferson.

Reference Committee on Reports of Secretary, Treasurer and Trustees—George A. Leitner, Rockland, Chairman, Charles L. Nichols, Columbia, Charles L. Davis, Genesee, Gustave A. Fensterer, Nassau, Mary D. Rose, New York.

Reference Committee on Report of Committee on

Legislation—Terry M. Townsend, New York, Chairman, Ralph E. Brodie, Orleans, W. Grant Cooper, St. Lawrence, John A. Hatch, Yates, George B. Stanwix, Westchester.

Reference Committee on Report of Committee on Public Health and Medical Education—Henry S. Patterson, New York, Chairman, Reeve B. Howland, Chemung, Robert DeCece, Erie, Charles R. Barber, Monroe, A. Sloan, Oneida.

Reference Committee on Report of Committee on Scientific Work—Arthur J. Bedell, Albany, Chairman, George S. Lape, Broome, Carl Boettiger, Queens, Dudley R. Kathan, Schenectady.

Reference Committee on Reports of Council and Censors—Leon M. Kysor, Steuben, Chairman, Frank L. Eastman, Ulster, Addison H. Bissell, Otsego, Joseph B. Hulett, Orange, Elias H. Bartley, Kings.

Reference Committee on Reports of Councilors—Chauncey R. Bowen, Allegany, Chairman, Frank Guillemont, Niagara, Albert W. Ferris, Schuyler, William H. Cantle, Westchester, V. S. Hayward, Bronx.

Reference Committee on Report of Legal Counsel—J. Richard Kevin, Kings, Chairman, I. J. Landsman, Bronx, Charles E. Scofield, Kings, Willard H. Veeder, Monroe.

Reference Committee on Report of Committees on Medical Economics, Public Relations, and Cardiac Diseases—Floyd S. Winslow, Monroe, Chairman, James Pedersen, New York, Robert M. Elliott, Seneca, Luther C. Payne, Sullivan, J. Leonard Byrnes, Washington.

Reference Committee on Report of Special Committee on Nurses—William A. Jewett, Kings, Chairman, William R. Thomson, Wyoming, Charles R. Borzilleri, Erie, Aaron Sobel, Dutchess-Putnam, William M. Patterson, New York.

Reference Committee on New Business—A—John Douglas, New York, Chairman, Howard T. Langworthy, Kings, Lucius H. Smith, Wayne, S. S. Ham, Schenectady.

Reference Committee on New Business—B—Robert H. Halsey, Chairman, Raymond C. Almy, Cayuga, Thomas N. Jenkins, Albany, Alec N. Thomson, Kings, Ward B. Hoag, New York, E. R. Cunniffe, Bronx.

Reference Committee on New Business—C—Thomas P. Farmer, Onondaga, Chairman, Baldwin Mann, Erie, R. Paul Higgins, Cortland, Alton B. Daley, Greene, James P. Brady, Monroe.

*The Secretary* I move that the reports, as they all have been printed, be referred to the respective committees without reading.

Seconded and carried.

### 6 RESOLUTIONS REGARDING COSMETICS—DR. HUBBARD

*The Vice Speaker* Is there any new business to be brought before the House of Delegates?

*Dr S. Dana Hubbard* With the permission of the House I would like to present the following resolutions for adoption.

WHEREAS, Attention has been called, from time to time, through the courts, newspapers and scientific magazine articles, of cases of dermatological irritation and poisoning through the use of cosmetics containing dangerous chemicals,

And, WHEREAS, Illness and deaths have been occasioned through such practices, and harm almost invariably follows such practice,

And, WHEREAS, Physicians and public health departments have in numerous instances analyzed package preparations of proprietary articles sold for personal

the education of the American public on this vital question.

*The Vice-Speaker* Referred to Reference Committee B on new business (Report in Sec. 16)

#### 11 ATTENDANCE OF DELEGATES AT THE AMERICAN MEDICAL ASSOCIATION

*Dr Chalmers* I have here, Mr Speaker, another resolution

WHEREAS, In the past years one or more delegates of this Society to the American Medical Association have not attended the meetings of the House of Delegates of the American Medical Association, and

WHEREAS, The roll call of the delegates to the American Medical Association is held on the afternoon of the fourth day of the meeting of the House of Delegates of the American Medical Association for the election of officers,

*Therefore Be It Resolved*, That any member of this Society permitting his name to be presented for election as a delegate to the House of Delegates of the American Medical Association, pledges himself that, in so far as it is within his power, he will attend all meetings of the House of Delegates of the American Medical Association that may be held during the term for which he was elected as such delegate Referred to Committee A on new business (Report in Sec. 24)

#### 12 NASSAU COUNTY'S LAY SECRETARY

*The Vice-Speaker* Is there any further new business?

*Dr Fensterer, Nassau County* I have the following resolution

WHEREAS, The Medical Society of the County of Nassau has for a period of more than three years employed a salaried layman as Executive Secretary, and

WHEREAS, It is the unanimous opinion of the members that during this period, the secretarial duties have been more thoroughly and satisfactorily performed than it would be possible to expect were a busy practicing physician responsible for such a task, and

WHEREAS During the cited period the society has evidenced the most encouraging growth in membership, attendance at meetings, and cohesive enthusiasm, which flourishing condition we attribute in no small measure to the efficiency of the secretarial office, and

WHEREAS, It has come to the attention of the Society that the Medical Society of the State of New York has declined to recognize officially this lay Executive Secretary, now therefore

*Be It Resolved* That the delegates of the Medical Society of the County of Nassau be, and hereby are, instructed to take such steps as may be necessary to bring to the attention of the House of Delegates of the 1927 Annual Meeting of the Medical Society of the State of New York the many advantages which it enjoys by reason of the efficiency of its lay Executive Secretary, and as a constructive suggestion to urge upon the other component county societies that they give thoughtful consideration to the advisability of the employment of such a person, and be it further

*Resolved*, That the said delegates be instructed to do all in their power to bring about a change in the policy of the Medical Society of the State of New York to the end that it may hereafter be the privilege of each component county society to elect if it so desires, either a physician secretary or a lay executive secretary, in either case the person so elected to be fully and completely recognized as the secretary of the society in all official matters wherein a secretary shall have jurisdiction

*Dr Trick* You offer this as an amendment?

*Dr Fensterer* I offer it as a resolution and amendment to the existing by-laws

*The Vice Speaker* Any amendment to the Constitution and By-Laws will lay over a year

*Dr Fensterer* That is for the Legislation Committee to recommend We only ask you to recognize our lay secretary If there is any legislation that would be necessary, that I believe would be the prerogative of the Legislative Committee as appointed

*The Secretary* Mr Speaker, this is an amendment, the whole resolution is an amendment to the Constitution, as it is a provision that a layman can be elected secretary of a County Society Therefore it cannot be taken up as a resolution It must come up, sir, as an amendment to the By-Laws or Constitution, whichever class it is, and lay over for a year, and necessarily will have to be presented as an amendment.

*Dr Fensterer* I will present it as such I present it as an amendment.

*The Vice-Speaker* It will have to lay over for a year

*The Secretary* Apropos of the resolution and amendment offered by Dr Fensterer, I move that a copy of this be referred to the Committee on Revision of Constitution and By-Laws, and that this action be taken with all such matters presented to this meeting, and all other suggested amendments

Seconded and carried.

#### 13 NASSAU COUNTY COMMENDATION OF GRADUATE INSTRUCTION COURSES

*Dr Fensterer* I have another resolution, this is not any recommendation of change of By-Laws, it is something we are going to thank the Society for

WHEREAS, The Medical Society of the County of Nassau has enjoyed and been greatly benefited by a series of weekly post-graduate lectures during the months of January, February, March and April, 1927, and

WHEREAS, This course was supplied without cost to us by the Committee on Public Health and Medical Education of the Medical Society of the State of New York, and

WHEREAS, this County Society recognizes fully the great amount of detail required to arrange an unbroken series of lectures over such a period of time, now therefore be it

*Resolved*, That the members of the Medical Society of the County of Nassau shall now give cordial and unanimous voice to their appreciation of the service rendered to them by the Committee on Public Health and Medical Education of the Medical Society of the State of New York, and similarly express their gratitude to each of the speakers who have come to them by instructing their duly appointed delegates to the 1927 Annual Meeting of the Medical Society of the State of New York to present these resolutions on the floor of the House of Delegates of the said meeting

We enjoyed those meetings, they were wonderfully instructive, and we are going to continue them

*The Vice-Speaker* This requires no action

*The Secretary* It will be placed on file.

#### 14 KINGS COUNTY—PUBLICITY IN THE NEW YORK STATE JOURNAL OF MEDICINE

*Dr Goodrich, Kings* WHEREAS, the minutes of the Medical Society of the County of Kings show that the Medical Society of the State of New York, through its regularly authorized officials, has twice within a year refused to open the columns of its Journal to publish therein resolutions which had been regularly carried by the component Medical Society of the County of Kings, and,

WHEREAS, The membership of the Medical Society of the County of Kings feels aggrieved at this refusal to acquaint other component county societies of the alternative measure to the Webb-Loomis Medical Practice Act and further, to its reasons for opposing the Webb-Loomis Act, and,

WHEREAS, The continuation of such an attitude would be prejudicial to the good feeling which must always

resulting from the present administration of the Bureau of Nursing of the Board of Regents of the State of New York. The increasing power granted by the Legislature to this Bureau has resulted in an autocratic control of the nursing profession. The work of Hospitals and Training Schools for nurses has become so handicapped under the administration of this Bureau as to severely curtail their former efficiency. The care of the sick has been subordinated in creating standards which should only be applied to the administrative and teaching nurse.

The interference in the management of local hospitals has created an intolerable situation to which the attention of the Governor and Legislature of this State is respectfully called.

Wherefore, the Medical Society of the County of Westchester at a regular meeting held at Bronxville on April 19th, 1927, resolved that legislation be suggested to establish a Board of Nursing Administration, quite independent of the Board of Regents. That the personnel of this Board of Nursing Administration be appointed by the Governor or Legislature on the nomination of

- 1 The New York State Nurses Association
- 2 The Medical Society of the State of New York.
- 3 The New York State Hospital Association

That the details of this proposed relief legislation be worked out by a joint Committee appointed by the three societies mentioned.

That the Medical Society of the County of Westchester instructs its delegates to present these resolutions at the May Meeting of the State Society and attempt to organize a Committee to further the enactment of this relief legislation.

That copies of these resolutions be forwarded to the Governor and the Westchester County members of the Legislature and to the Presidents of the three Societies mentioned.

Signed, Harrison Betts, Secretary

The Vice-Speaker Referred to Reference Committee on New Business (Report in Sec. 26)

#### 9 COMMITTEE ON REVISION OF CONSTITUTION AND BY-LAWS

*Dr Kopetsky, New York* In view of the fact that there have been in the last number of years amendments to our Constitution and By-Laws, all of which are rather scattered, and in view of the fact that there are amendments presented today which must necessarily lay over for a year before being considered, I move you, sir, the appointment of a committee to revise the Constitution and By-Laws—a committee of five appointed by the Speaker to report to the House of Delegates at the next annual session.

*The Secretary* I would recommend—I don't want to make an amendment, but I would recommend that in appointing a committee of that kind, the appointment be made by the President.

*Dr Kopetsky* I am willing to accept the suggestion. Seconded and carried.

#### 10 PRESCRIPTIONS FOR ALCOHOL

*Dr Chalmers, Queens* I offer the following resolution.

WHEREAS, The Congress of the United States, under the authority of the Eighteenth Amendment to the Constitution of the United States passed an enabling act known as the Volstead Law, and

WHEREAS Said Volstead Law provided, in part, that "No physician may prescribe more than one pint of spirituous liquor to be used by a patient within any period of ten days" (Section 7, Title II, National Prohibition Act, 41, Statute 305) and,

WHEREAS, The Supreme Court of the United States has decided by a majority of five to four in the case of Lambert vs Yellowley that the Congress has power to

limit the amount of whisky which a physician may prescribe for a patient to one pint in ten days, irrespective of the patient's condition or the physician's opinion as to the patient's needs, and

WHEREAS, In the course of the minority opinion of the Supreme Court, Mr Justice Sutherland said,

It is now said by the majority (of the Court) at one point, that the preponderating opinion of practicing physicians is against the use of all three (spirituous, vinous and malt liquors) and, at another point, that only a minor fraction hold the other view. I am quite unable to assent to these generalizations. On the contrary, the impossibility of determining from anything now before the Court what is the preponderating opinion upon this subject, is very clear," and

WHEREAS, The assumption by the Congress in the enactment of the Volstead Law, of the right to limit the amount of spirituous or vinous liquors which physicians may prescribe as therapeutic agents in the treatment of disease, is dangerous, hazardous and detrimental to the public health, and

WHEREAS, In view of this decision of the Supreme Court, no one is able to foresee to what extremes of restrictive legislation the Congress may go or what drug, therapeutic agent or professional privilege may be curtailed, and

WHEREAS, Whisky, brandy and vinous liquor are included in the list of drugs in the latest edition of the United States Pharmacopoea and are necessary therapeutic agents in the treatment of disease, and

WHEREAS, The limitation of the therapeutic use of these drugs is not within the purview of the National Prohibition Law or the Volstead Act, which relate to the control of the use of spirituous or vinous liquors for beverage purposes, and

WHEREAS, It is recognized as the right of the Congress to enact such laws and regulations as will prevent the diversion of spirituous or vinous liquors for beverage purposes only, provided there be not thereby curtailed the right of the physician to prescribe and administer in good faith such liquors in such amount and dosage as in his scientific judgment the need of his patient may require, and

WHEREAS, It is not only the right but the sacred duty of Americans, inheriting as they do, the inestimable privileges of Anglo-Saxon liberty, to petition for a redress of grievances,

Therefore, *Be It Resolved*, That the House of Delegates of the Medical Society of the State of New York at its annual meeting at Niagara Falls on May 9th, 1927, and representing as it does more than ten thousand duly licensed physicians of this State, mindful as it is of the solemn duty of the doctor to render to his patient whatever treatment the true teachings of science declare to be necessary or beneficial in caring for the sick and resenting with stern disapproval any arbitrary and unscientific curtailment of this obligation, realizing full well that to prevent the physician by arbitrary regulation from using for his patient's benefit whatever therapeutic agent his scientific knowledge and his conscience dictates, emphasizing its disassociation with any political issue, commonly referred to as "wet" or "dry," in unmeasured terms condemns this unjust, unwise, unsound, arbitrary and unscientific curtailment of and reflection upon the medical profession as a whole, and therefore, not in its own behalf but in that of the lay public, whom it seeks to serve, earnestly petitions for the immediate repeal of this section of the Volstead Law, and

*Be It Further Resolved*, That the delegates from New York State to the House of Delegates of the American Medical Association be instructed to present and by all proper means to advocate the adoption of a memorial to the Congress of the United States, demanding the immediate repeal of that Section of the Volstead Law and to employ all legitimate and honorable means for

ciation that may be held during the term for which he was elected as such delegate

The Committee feels that it is understood when a man is elected as a delegate he expects and intends to be present at the meeting of the American Medical Association and therefore such resolution is unnecessary and is not recommended.

I move it be not recommended

*The Secretary* Point of order You cannot recommend a negative motion. The correct motion is to adopt the report

*The Speaker* Point of order is well taken

*Dr Douglas* I move the adoption of the report  
Seconded and carried.

## 25 REFERENCE COMMITTEE ON REPORTS OF COUNCILLORS

(The reports were printed on page 481 of the May 1 JOURNAL.)

*Dr Bowen* Reference Committee on Reports of Councillors has examined in detail the reports of the eight District Branches. We find that an annual meeting was held by each of the Branches. The officers of the various branches have evidently pursued their labors with industry, with a conscientious regard for their positions, and with a constant loyalty to our State organization

The following suggestions were made by our committee. In view of the fact that the meetings on the average have not been well attended, we recommend that a program varied in character to attract men practicing in general medicine and of interest and value to the general practitioner should be constructed

Frequent meetings of the Executive Committees of each branch as recommended by the President of the Eighth District Branch are advisable in order to stimulate more interest in these District Meetings

I move the adoption of the report Seconded and carried.

## 26 WESTCHESTER COUNTY'S RESOLUTION ON A STATE BOARD OF NURSING ADMINISTRATION

*Dr Farmer* The Reference Committee on New Business C has considered the resolution of the Medical Society of the County of Westchester (Sec. 8) suggesting the establishment of a Board of Nursing Administration quite independent of the Board of Regents

The Committee feels that training schools for nurses are educational institutions and therefore properly belong under the direction of the Board of Regents of the State of New York, and therefore disapproves the recommendation

The Committee respectfully suggest that the Medical Society of the State of New York request the Board of Regents to appoint an advisory committee to the Bureau of Nursing of the Board of Regents, said committee to have a representative of

- (1) The New York State Nurses' Association
- (2) The Medical Society of the State of New York,
- (3) The New York State Hospital Association, for the purpose of remedying evils or abuses of poor administration of that bureau which may exist

I move the adoption of this report

*Dr Cottis* I oppose very strongly any such action. The Committee apparently is acting under the theory that this is purely an educational question. As I understand the theory of the Westchester County, their attitude is that this is a question of dictation to us as to what nurses we may employ and on what disease we may employ them. It is a question whether this bureau in Albany can say that we shall not accept nurses from over the line in Pennsylvania or New Jersey unless the training school from which they come consent to an inspection by New York State Nursing Bureau employees

I think the Committee has not thoroughly understood the reason back of this motion. We two years ago argued two or three hours on this question of nursing control, and I think this should be very thoroughly discussed before the report of the committee is adopted

I would very strongly favor the action of the Westchester County Society in advocating the establishment of a bureau in which the Medical Society of the State of New York may have some interest

*Dr Trick* It seems to me this should be taken up in two parts. It seems to me the latter part was really a different proposition and if we might discuss it in that way it would probably simplify the proceeding

*Dr Farmer* I move the recommendation of the first part.

*The Vice-Speaker* The part of this report under discussion will be that part of the resolution from Westchester County regarding the establishment of this bureau of which the Committee does not approve.

*Dr Van Kleeck* Last year in the House of Delegates there was a ruling on nurses that each county should establish a local registry that would not replace the commercial registry that already existed, but would have supervision of all the nurses operating within that district. Such a registration should be under the control of the county society of that district. Is there any relation there to this resolution now before the House?

*Dr Dyer* The Superintendent and Directors of Nurses of Jefferson in Philadelphia and of the University of Pennsylvania Hospital told me that they wished to have their nurses registered in New York State. They made overtures to the Department at Albany. The nurses there, I might say, all have to take three years training and not only that but have to be graduates of a high school, the standards being greater than those of New York State. Also the nurses in Philadelphia are receiving a compensation of \$35 a week, and they seem to be willing to work at that rate. If those nurses would come up here in New York State it would furnish us an extra supply of nurses, and the nursing departments of these respective hospitals were willing to have them registered. But owing to various little annoying requirements from Albany, in disgust, they finally threw the thing up and have nothing more to do with it at all. I don't think we understand the pernicious influence of this department at Albany

*Dr Farmer* I might say in presenting the second resolution, which we are now considering, we have in mind what Dr Cottis spoke of. We thought that these things may occur—we were pretty sure they did occur

We felt the proper way to handle the situation was to get more information for a better action at a later time, and such an advisory committee could handle that very well

*The Vice-Speaker* Does that seem to meet your idea, Dr Cottis?

*Dr Cottis* No, it does not. I don't think the word "Advisory Committee" fills the situation, because the Bureau at Albany is not susceptible to advice from any medical men. I would suggest, if I might, if that is the purpose of the Committee, you have another committee to consider it. We have done that for three years, and we find we must have some way to subdue the bureaucracy at Albany. If you want to get at the situation and find out how we are being handicapped that is different. I would suggest that "Advisory Committee" be "Investigating Committee"

*The Secretary* The Speaker requests me to state that he wishes this to be taken from the committee to which it was referred, and referred to the Reference Committee on Nursing, so that the whole question can be thrashed out by that committee. I so move Seconded and carried (See Sec. 40 and 41)

## 27 REFERENCE COMMITTEE ON COMMITTEE ON SCIENTIFIC WORKS

*Dr Bedell* Reference Committee on Report of Committee on Scientific Work has considered the report in question and recommends the excellent program arranged. Your committee approves the report and moves its adoption. Seconded and carried

A twenty-minute recess was then taken

exist between the Medical Society of the State of New York and the component county societies, be it

*Therefore Resolved*, That the Medical Society of the County of Kings hereby asks the Medical Society of the State of New York to direct the columns of its Journal be always open for the publication of resolutions adopted by county societies when requested and that on moot matters affecting the welfare of all practicing physicians of the State of New York its columns be impartially open to opponents and proponents of pending legislation

*The Vice-Speaker* Referred to Reference Committee A on New Business (Report in Sec. 28)

#### 15 PROTEST AGAINST THE MILLER BILL AMENDING THE WORKMEN'S COMPENSATION LAW

*The Vice-Speaker* Is there any other new business? If there is none, are any of the reference committees ready to report?

*The Secretary* I have a letter, Mr Speaker, just received by registered mail I don't know what it is, but it is addressed to the Annual Meeting Shall I read it?

The Secretary read the letter signed by the following physicians of Erie County, protesting against the Miller Bill to amend the Workmen's Compensation Law Edward E. Haley, John V. Woodruff, M. J. Helminiak, Charles Leone, R. L. Cooley, Joseph Burke, Charles W. Bethune, William Priess, L. Edward Villaume, M. A. Sullivan, William K. O'Callahan, H. J. Hammond, Francis J. Butlak, J. M. Flannery, James E. Dolan, James P. Kinney, H. D. Duryea, W. F. Burke, L. H. Chely, M. J. Littlefield, S. A. Moore, F. J. Carr, J. C. Sullivan, J. L. Gallagher, James W. Nash, Francis Argus, Edward A. Twist, F. J. Rice, James J. Brown, Eugene J. Hanavan, W. G. Grove, Alfred Luhr, C. D. Moses, A. R. Gibson.

*The Vice-Speaker* None of these men are members of the House of Delegates. It is rather doubtful as to giving it a place in our proceedings. It might be referred to one of the committees on new business.

I so move. Seconded and carried (Report in Sec. 30)

*The Vice-Speaker* Referred to reference committee B on new business

*The Vice-Speaker* Is there any other new business? If there is none, is any reference committee ready to report?

#### 16 REFERENCE COMMITTEE ON PRESCRIPTIONS FOR ALCOHOL

*Dr Halsey* Reference Committee B on New Business, after studying the resolution regarding prescribing of spirituous liquors introduced by Dr Chalmers (Sec. 10), recommends to the House of Delegates that action be taken as recommended in the resolutions

Seconded and carried

#### 17 REPORT OF REFERENCE COMMITTEE ON THE REPORT OF THE SECRETARY, THE TREASURER, AND THE TRUSTEES, PUBLICATION OF JOURNAL AND DIRECTORY

(The reports were printed in the JOURNAL of May 1, on pages 456, 458, and 461)

*Dr Mary D. Rose* We heartily commend the efficient work of our Secretary as incorporated in his annual report. We approve of the recommendations of the Secretary that the printing of the Directory and Journal be placed under our Publication Department, and that a proper Financial Department be formed for the same.

#### 18 CHANNELS FOR TRANSMITTING REPORTS

We approve of the suggestion of the Secretary that all reports and official communications go through regular organized channels and we respectfully request that all such be sent to the Society's office, and furthermore recommend that all resolutions and motions be in writing and in duplicate, one for the Reference Committee and one for the Secretary's file.

#### 19 HONOR COUNTIES

We especially wish to emphasize our honor counties, Cayuga, Chemung, Delaware, Essex, Fulton, Greene, Lewis, Nassau, Orleans, Rockland, Schoharie, Schuyler, Seneca and Thompsons

#### 20 TREASURER'S REPORT

We recommend that the Report of the Treasurer be accepted as printed in the State JOURNAL.

I move the report be adopted.

Seconded and carried

#### 21 ELECTION OF RETIRED MEMBERS

*The Secretary* While we are waiting, I move the election of the following retired members. These gentlemen have passed the age of seventy years and have been recommended by their several counties: Dr Thomas Bagley, of Buffalo, Dr De Lancy Carter, of New York City, Dr Lucien Howe, of Buffalo, Dr George H. King, of Watkins Glen, Dr Francis J. Quinlan, of Amawalk, Westchester County. Dr Quinlan is a member of New York County. Dr Francis M. Rich, of Buffalo, Dr Henry Lewis of Argyle, Dr Marcus E. Tully, of Glen Ridge, New Jersey, a member of New York County, Dr John E. Weeks, Portland, Oregon, also a member of New York County.

I move the election of these gentlemen, as they have complied with all the qualifications for retired membership. Seconded and Carried

#### 22 REFERENCE COMMITTEE ON REPORTS OF THE COUNCIL AND CENSORS

(The reports were printed in the JOURNAL of May 1, pages 460 and 461)

*The Vice-Speaker* Any other Reference Committee ready to report?

*Dr Kysor* The Reference Committee on Reports of Council and Censors unanimously endorse the report of the Council.

We also unanimously endorse the report and action of the Board of Censors.

This Committee notes the mounting annual loss of the publication of the Directory, but make no recommendation relative to it because it has been thrashed out so many times.

I move the adoption of the report. Seconded and carried

#### 23 CONTROL OF COSMETICS

*Dr Douglas* Reference Committee A on New Business recommend the adoption of the resolution affecting the sale and use of cosmetics containing dangerous chemicals, (Sec. 6) and recommend that the State delegates to the American Medical Association be instructed to present the necessary resolutions at this meeting so suggested.

I move its adoption. Seconded and carried

#### 24 ATTENDANCE OF DELEGATES TO THE AMERICAN MEDICAL ASSOCIATION

*Mr Douglas* With regard to the following resolution offered by Dr Chalmers (Sec. 11)

WHEREAS, in the past years one or more delegates of this Society to the American Medical Association have not attended the meetings of the House of Delegates of the American Medical Association, and

WHEREAS, the roll call of the delegates to the American Medical Association is held on the afternoon of the fourth day of the meeting of the House of Delegates of the American Medical Association for the election of officers,

*Be It Therefore Resolved*, that any member of this Society permitting his name to be presented for election as a delegate to the House of Delegates of the American Medical Association, pledges himself that, insofar as it is within his power, he will attend all meetings of the House of Delegates of the American Medical Association.

In the first place, mortality, the figures of which are relatively easily obtained, and which we have requested, is of a relatively small amount—it means getting the figures from the Department of Health at Albany and tabulating those in such a way as to get matter that is of value in the consideration of the problems. That is the chief part of the work.

The next most important phase of the work is the one on morbidity. There are no figures or data to be obtained on morbidity excepting in very small groups of individuals, that is, school children, a few in industries, a few in insurance, and a few other small groups. None of them carry the consideration of all-age groups.

To get those facts it will mean the expenditure of considerable funds and of considerable time. It will probably take the best part of next year to gather any information of value on that. It means the adoption of the criteria as to what we are just going to mean by heart disease, the various kinds, ideological factors, and so on, all of which will mean time and money because you know very well that no physician can do that work, you have to get skilled workers who are able and properly trained to go into hospitals and to go wherever the information may be obtained. That has not altogether been worked out as to how we can get those facts. Money will not be spent unless we can be sure we are going to get facts commensurate with the outlay, and present that to you as soon as it can be done. That is the expensive part of the work and will require not only the work of this State committee and of the State problems, but of as many outside agencies as we can get to cooperate with us. I might say here that all the State groups that have to do with public health or hospitals have been very cooperative with this committee and have given us a great deal of assistance in gaining the information that we have been able to gain so far, and they will continue to help us get information as soon as we can outline a plan for that work.

*Dr Higgins* I think Dr Bedell is right in drawing attention to the fact that no committee, no matter how eminent its members, should be given a free hand in spending money, and I think before adopting this resolution I would move this committee be limited to a certain sum of money, or not to exceed a certain sum of money.

*The Vice-Speaker* We recommend to the Board of Trustees an unspecified amount.

*Dr Phillips* Dr Bedell's question is a perfectly proper one, but the best answer to it is that last year we established a Board of Trustees, men in whom we have confidence, and I think we are perfectly safe in trusting the Board of Trustees as to any appropriations that are made, that they will be adequate and not be excessive. It seems to me that it has very little to do with the adoption of this report because all finances are referred to the Board of Trustees.

*The Secretary* I would also like to call attention to the By-laws which distinctly state that all appropriations must be made by the Trustees. We cannot recommend anything as a House of Delegates to them positively with the idea they will carry it out. They may say, "No, this work cannot go on, and we won't give you five cents," and the House of Delegates, the Council or no other body can object to it. It is entirely in the hands of the Trustees.

*Dr Bedell* We are delegates sent by our County Society. It would certainly seem right and proper that we as delegates should be informed as to how their money is spent. It is not a question whether our Board of Trustees spends the money. It is a question that this is the first time that this Society, acting under the Board of Trustees, has appropriated this unknown sum of money. I think gentlemen, as a whole, you will agree it is a fair proposition that we should know what our Trustees are doing. I see nothing in here that tells us our Board of Trustees have made recommendations

of this, that or the other sum of money. As stockholders in any concern, we would have a report.

After further discussion by Drs Mabbott, Bedell and others, the report of the committee was adopted.

### 32 ESTABLISHMENT OF A COMMITTEE ON PUBLIC RELATIONS

(The report is printed in the JOURNAL of June 1, page 621.)

*Dr Winslow* The resolution authorizing the creation of a standing committee on Public Relations

WHEREAS, effective practice of preventive medicine requires harmonious cooperation of the medical profession and interested agencies both official and voluntary and many new situations and conditions are continually arising in whose solution there may be differences of opinion, and

WHEREAS, it has happened that where no opportunity was afforded for mutual or common consideration of the methods employed in promoting programs of preventive medicine or public health that occasionally much time and energy have been lost through misunderstanding and criticism by some, of the plans of others, and

WHEREAS, it has been found that many times such criticism has resulted from ignorance on one, or on both sides, of the plans, purposes and objections of the other, and

WHEREAS it has also been found that where some such problems have been considered in conference, harmony in procedure was not difficult to attain, therefore,

*Be It Resolved*, that there be created by the House of Delegates a permanent standing committee of five members and the executive officer member ex officio, to be known as the Committee on Public Relations and that it shall be the function of such committee to deliberate with other agencies both official and unofficial concerning the plans, purposes and objectives of their organizations inasmuch as they have a relation to the medical profession, and

*Be It Further Resolved*, that each County Society be recommended to name a committee of its members for a similar function in its district.

I move the adoption of this resolution (Sec. 50)

*The Secretary* It is an amendment to the Constitution and By-laws

*The Vice-Speaker* Yes, it must be referred to this committee.

*The Secretary* And also be accepted as notification of an amendment

*Dr Winslow* I move we approve it and refer it to the Committee on Revision of Constitution and By-laws Seconded.

*Dr Jenkins* You mean to approve the creation of another committee?

*The Vice-Speaker* Yes a standing committee known as the Committee on Public Relations. Motion carried

### 33 DEMONSTRATION CLINIC IN PERIODIC HEALTH EXAMINATIONS

*Dr Winslow* Reference Committee on Report of the Committee on Medical Economics has studied the report and recommends that the House of Delegates approve the establishment of a Demonstration Clinic in different parts of the State in order to determine the value of the plan. We also recommend that a course of instruction in physical examinations be added to the curriculum of schools of medicine in this State.

I move the adoption of this resolution. Seconded and carried

### 34 REPRESENTATIVE IN THE COMPENSATION CONFERENCE

*Dr Winslow* Your committee recommends that the House of Delegates approve the appointment of a representative from the State Medical Society to the Compensation Conference.

I move the adoption of this resolution. Seconded

*The Vice-Speaker* Is there any reference committee ready to report?

## 28 REFERENCE COMMITTEE ON PUBLICITY IN THE STATE JOURNAL

*Dr Douglas* The Committee on New Business A recommends that the resolution in regard to publicity in the State Journal (Sec. 14) be referred to the new committee for the revision of the Constitution and By-laws, for incorporating in same such safeguards of the rights of the County Societies to publicity in conformity with the interests of the State Society

I recommend its adoption Seconded and carried

## 29 REFERENCE COMMITTEE ON REPORT OF COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

(The report was printed on page 464 of the May 1, JOURNAL)

*Dr Henry S Patterson* Reference Committee on Report of Committee on Public Health and Medical Education, desires, first, particularly to draw attention to the broad field of this committee's endeavor as shown by the wealth of subjects covered, and, second, to the many counties of the State in which instruction has been given

The report shows in a graphic way the subjects and the territories involved and speaks eloquently for itself

Your reference committee wishes to emphasize the point made in the report under consideration that the medical profession is the agent that is and should be present in all public health activities, and without its cooperation such movements, no matter how worthy, are robbed of their real effectiveness As an example of the applicability of this principle, your reference committee draws attention to the excellent work done by the Committee on Public Health and Medical Education in fostering the campaign for immunization against diphtheria by toxin, anti-toxin, and we maintain that if, in certain districts the results have not reached expectations, it is due to the lack of initiative on the part of individuals, in spite of the stimulus given by this committee In corroboration of this opinion we draw attention to the statement of the report that in only a small minority of counties has a definite program against diphtheria been adopted Your reference committee is fully aware of the necessity for press cooperation, and entirely approves of any such activity as has been carried out by the Committee on Public Health and Medical Education It makes the plea that any communications on medical subjects to the lay press be made only with the knowledge and consent of the accredited authorities of national state or county associations

In specially commending the work of the Committee on Public Health and Medical Education, the hearty cooperation of the State Department of Health, the Medical Society of the County of Kings, and the sixty-five members of this society who have carried out the instruction at great personal sacrifice, I move the adoption of this report. Seconded and carried (Sec. 49)

## 30 PROTEST AGAINST THE MILLER BILL AMENDING THE WORKMEN'S COMPENSATION LAW

*Dr Halsey* Reference Committee on New Business B has considered the "Letter of Protest" from the County of Erie (Sec 15) and recommend that it be laid on the table.

*The Secretary* The Speaker rules it would be out of order

*Dr Halsey* The Committee recommends it be laid on the table. I know of no other way a reference committee can act than by a recommendation. Seconded.

*The Speaker* The motion to lay it on the table is out of order when recommended as the report of the Committee.

*Dr Halsey* The matters contained in that communication are of such a nature that it is not a matter for this House to do other than to simply lay it aside The matter is not framed in such a way that the committee

can make a recommendation that it be denied or concurred in, or not concurred in, unless we take it up seriatim and that seemed unwise, as there are no matters that the committee could in any way favor It is outside the province of this organization, to discuss them, unless the report is desired to be read and discussed article by article.

*The Speaker* Referred back to the Committee for reconsideration (See Sec. 42)

## 31 REFERENCE COMMITTEE ON REPORT OF COMMITTEES ON MEDICAL ECONOMICS, HEART DISEASES AND PUBLIC RELATIONS STUDY OF HEART DISEASES

(The report was printed on page 468 of the May 1 JOURNAL.)

*Dr Winslow* Reference Committee on the reports of the Committees on the Medical Economics, Special Committee on Heart Diseases and the Committee on Public Relations A resolution authorizing the appointment of a Special Committee to study diseases of the heart (Sec. 51)

WHEREAS, compilers of vital statistics have noted with concern for a number of years a marked increase in the number of deaths attributed to diseases of the circulatory system, and

WHEREAS, the mortality from most infectious diseases is greatest in the early and late periods of life, while the mortality from heart disease is greatest in the prime of life, and

WHEREAS, during 1925, in the State of New York, more deaths were reported under this general group than from any other, not excepting, even, the group of endemic, epidemic and infectious diseases, in which are included tuberculosis, cancer, diabetes mellitus, diphtheria and all infectious diseases of childhood The total number of deaths reported during the year was 142,426, of which 36,184, or 25 per cent., belonged to the first group and 35,754 to the second group From diseases of the heart alone, the death rate in 1925 was 268.9 per 100,000, an increase of 20.8 over the average annual death rate in the five preceding years And from diseases of the arteries, the death rate in 1925 was 51.4 per 100,000 an increase of 4 deaths per 100,000 over the annual average for the five preceding years, and

WHEREAS, the physicians, members of this Society, have been doing their utmost individually to stem this rising death rate from circulatory diseases, and

WHEREAS, a special committee of nine members, eminently qualified through scientific training and clinical experience has, during the last year, entered upon a study of the situation in this State and has prepared a comprehensive plan for further investigation.

*Be It Therefore Resolved*, that this special committee as constituted, be authorized to continue its study during the coming year in accordance with the plan submitted, and

*Be It Further Resolved*, that the Board of Trustees be recommended to set aside an appropriation sufficient to meet the necessary expenses of the committee's operation in that time

I move the adoption of this resolution Seconded  
*Dr Bedell* I rise for some information I note in the committee's report it says a sufficient sum. Just before I left home I read in my daily paper this House of Delegates was going to allow the sum of seven thousand dollars for this committee. If a single committee of this House is to be allowed seven thousand dollars, I do believe we should know something about the committee's work. Now, that does not cast any aspersion on any member of the committee It is simply a new thing for any committee in this House to be granted a large sum of money of that sort, and I think we would like the chairman of this committee to give us some information

*Dr Halsey* The study of the problem of heart diseases requires the study of two phases of public life

4 Endorsement and encouragement of visiting nursing service

5 Thorough trial by all of the members of the Medical Society of the State of New York, of hourly or part-time nursing with broad publicity of its methods and possibilities

6 Group nursing in hospitals

7 That the period of training be twenty-eight months, the first four to be devoted to concentrated study of fundamental anatomy, bacteriology, physiology, chemistry and dietetics, and that the succeeding two years be devoted as far as possible to teaching the art of nursing by demonstration, participation and practice

8 That a committee be formed to study the curriculum, the committee to be composed of three physicians appointed by the President of the Medical Society of the State of New York, three nurses appointed by the New York State League for Nursing Education, and one representative of the Department of Education who shall be neither physician nor nurse.

I recommend the adoption of this report.

Seconded and carried

#### 41 WESTCHESTER COUNTY RESOLUTION ON A STATE BOARD NURSING ADMINISTRATION

*Dr Jewett* The resolution of the Medical Society of the County of Westchester referred to committee on new business C was then referred to the Special Committee on Nursing

It is the sense of this committee that the spirit of the resolution presented by the Medical Society of the County of Westchester (Section 8), is embodied in the findings of the committee, suggested under recommendation number 8 and we also advise that the Medical Society of the County of Westchester continue their efforts toward a solution of their local problems

I move the adoption.

Seconded and carried

#### 42 PROTEST AGAINST THE MILLER BILL

*Dr Halsey* Reference Committee on New Business B has considered the "Letter of Protest" from the County of Erie (Secs 15 and 30) and believe it to be a matter for action of the County Society and not for the House of Delegates and therefore recommend that the communication be placed on file

I move the adoption of this report.

Seconded and carried.

#### 43 REFERENCE COMMITTEE ON REPORT OF LEGAL COUNSEL

(Report in May 1 JOURNAL, page 478)

*Dr Kern* Reference Committee on Report of Legal Counsel finds that the report of legal counsel with its various and numerous activities has been concisely and splendidly presented, which permits your committee to add but little to the presentation of the report. There are no recommendations requested. There are some factors, however, which your committee feels may be emphasized

Aside from the legal cases which come before the legal counsel in the usual proportion of suits to an insured membership of a little over six thousand his activities in aiding the Society from other angles are impressive. From the editorial standpoint he has given a digest of numerous malpractice cases through our JOURNAL besides giving at least seventeen editorial comments on live questions relative to "quacks" and illegal practitioners. His advice to the officers of the Society has been frequently given, his appearance at Albany at the hearing of all the important legislative questions and his visitations to a great many of the county societies throughout the State manifest to your committee that his heart is in his work and his enthusiasm has been exercised in the largest degree. Your committee is of the opinion that our selection and retention of the legal counsel has been wise and profitable

Your committee is also impressed with the report on the Group Liability Plan and the excellent work which has been accomplished through our insurance representative, Mr Harry F Wanvig. We desire to take this opportunity to call attention to the fact that only about 56 per cent of the membership has taken advantage of this excellent Group Liability Plan and we recommend that efforts be made in the way of propaganda in the county medical societies with a view to reaching and explaining the benefits of our Group Liability Plan

I move the adoption of the report

Seconded and carried

#### 44 REFERENCE COMMITTEE ON REPORT OF THE COMMITTEE ON LEGISLATION

(Report printed in May 1 JOURNAL, page 478)

*Dr Townsend* Your Reference Committee on Report of the Committee on Legislation heartily commend the work of that body during the past year. We particularly congratulate them for their success in preventing legislation inimical to the public health and the practice of medicine.

We especially approve of that portion of the report referring to the administration of the Medical Practice Act and physiotherapy

Your reference committee heartily endorses and hopes for a continuance of the close contact maintained between the State Legislative Committee and the Officers and Committee Chairman of the various County Societies

We wish to emphasize those paragraphs expressing thanks and appreciation to legislators, State Departments, and representatives of philanthropic bodies for their cooperation with the Committee on Legislation

We furthermore emphasize the tribute paid to our executive officer, Dr Joseph S Lawrence, for his untiring activities on behalf of our society

I move the adoption of this report.

Seconded and carried (Sec. 60)

*Dr Britt* I would like to ask about this letter referred to Reference Committee B on New Business, this letter that comes from Erie County, does it go into the printed report of this House of Delegates?

*The Secretary* No, filed in the Secretary's office that is all

#### 45 REFERENCE COMMITTEE ON PRESIDENT'S REPORT INVESTIGATIONS BY THE BOARD OF TRUSTEES

(The President's Address was printed on page 451 of the May 1 issue of this JOURNAL.)

*Dr Hicks* Reference Committee on the President's Report, endorse the suggestion that the Board of Trustees be authorized to provide means for informing itself from time to time concerning the expenditure of funds they have appropriated

*Dr Kopitzky* I move the adoption.

Seconded and carried.

#### 46 NAMES OF DISTRICT BRANCHES

*Dr Hicks* 2. Adverting to changing the names of the District Branch Societies to District Medical Societies this recommendation seems to be unnecessary so far as it relates to changing the names from District Branch to District Medical Societies. It would perhaps be confusing to many and its advantages not apparent, as some members might get the impression that the District Medical Society would represent a distinct organization independent of the State Medical Society and its component County Societies. However this might be left to the District Branch Societies for further consideration

*Dr Trick* I believe it is a question of organic law. It cannot be done.

*Dr Hicks* Then I won't refer to that.

#### 47 DISTRICT BRANCH CONFERENCES

3 Your committee is in accord with the suggestions that the President of the District Branch Societies fre-

*Dr Bedell* What is his power?

*Dr Winslow* That is contained in the report of the Committee on Medical Economics

*Dr Bedell* I move you, sir, the Chairman of this committee read that part for the edification of us all.

*The Vice-Speaker* Will you read that part referring to the suggested appointment?

*Dr Winslow* "A Compensation Conference composed of heads of various insurance companies, a delegate from the Medical Society of the State of New York, a delegate from the State Society of Industrial Medicine and representatives of labor organizations, was formed in January as the result of a preliminary meeting called by the State Industrial Survey Commission"

*A Delegate* I recommend an amendment as follows, that the delegate be instructed to report to the House of Delegates

Seconded.

*The Vice-Speaker* The original motion was that we appoint a delegate to this Conference

Motion carried.

### 35 COUNTY HEALTH UNITS

*Dr Winslow* Based on recent experience in certain counties as to the advantage of a County Health Unit it is recommended that the Medical Society of each County where no Health Unit yet exists, organize a committee to study the question in its County and to take the initiative in planning, organizing and supervising such County Health Unit in cooperation with the State Society

I move the adoption of this resolution

*The Secretary* That should not take in the five counties in the City of New York as the City Department of Health is an entirely separate unit. It would be impossible in those five counties

Motion seconded and carried

### 36 DISTRICT BRANCH FIELD SECRETARIES

*Dr Winslow* Your Committee finds the duties of officers of several County Medical Societies and District Branches are multiplying and require increased clerical assistance beyond the financial means of County Medical Societies. We therefore recommend that each District Branch consider the advisability of employing a field secretary to execute detail work of component county societies of each district

I move the adoption of this resolution.

*Dr Trick* That would necessitate the change of the By-Laws again

*The Secretary* We cannot do that until there is an amendment to our Constitution and By-Laws

*The Vice-Speaker* I suggest this be referred to the committee on Constitution and By-Laws

*Dr Winslow* I will make that motion

Seconded and carried

### 37 REFERENCE COMMITTEE ON REPORT OF COMMITTEE TO STUDY THE LAWS ON WORKMEN'S COMPENSATION

(Report printed on page 475 of May 1 issue of JOURNAL.)

*Dr Winslow* Your Committee on the report of the Special Committee to study the laws on Workmen's Compensation report as follows

We have considered the report of this special committee and we recommend that the Society endorse by adoption the plan laid down in the proposed Workmen's Compensation Medical Procedure Act. That Act was permissive in all its organization detail and mandatory only wherein it related to these special administrative details that bade fair to bring the Profession into disrepute, such as conflicts of medical testimony and kindred subjects

I move the adoption of this resolution

Seconded

*The Vice-Speaker* All those in favor of adopting the

report of this Committee, say Aye. Opposed, No. I am in doubt, we will have to have a standing vote.

A standing vote resulted in Ayes, 44, Noes, 53

### 38 WOMEN'S AUXILIARY ASSOCIATION

*Dr Fisher, President* We have with us two distinguished visitors, a lady from Pennsylvania and a lady from Texas, who are anxious to inaugurate a Women's Auxiliary in the State of New York, and if it is agreeable I would ask permission of the House that they may have a few moments to explain the work

*Dr Phillips* Before Mrs McReynolds, who is the President of the American Medical Women's Auxiliary Association, takes the floor, and Mrs Babcock of Pennsylvania, who has made such a success of the Women's Auxiliary work in the State of Pennsylvania, I wish to say to this House that the work of the Women's Auxiliary members of this Association has met with the approval of the officials of the American Medical Association.

I sincerely hope that the resolution which will follow the few remarks which they have to make will meet with the approval of this Society

Mrs William Wayne Babcock and Mrs John O McReynolds then addressed the House.

*Dr Fisher* One more innovation that your retiring president would like to make

*Resolved*, That the House of Delegates of the Medical Society of the State of New York, first, endorse the organization of the Women's Auxiliary in the State, second, that the delegates will urge the County Presidents to further the organization in their various counties, third, that the individual members make clear to their wives the wonderful opportunity of aiding the medical profession through the organized efforts of the Auxiliary

I move you, Mr Speaker, that this be referred to a committee

*The Vice-Speaker* The regular procedure would be that it be referred to one of the reference committees on new business, but I think if you desire we might suspend the By-Laws by two-thirds vote and take immediate action.

*Dr Fisher* I move the By-Laws be suspended.

Seconded and unanimously carried

*The Vice-Speaker* Now with regard to the resolution presented by President Fisher

Motion made, seconded and carried

### 39 MEMBER OF INDUSTRIAL CONFERENCE COMMITTEE

*Dr Kopetsky* On new business, I move you, since we have decided the Society shall be represented, that Dr Britt be our nominee to represent us on the Industrial Conference Committee.

*The Vice-Speaker* The only way to make that action legal is to again suspend the By-Laws

*Dr Kopetsky* This is not an amendment, it is a resolution. Your reference committee has reported I am making a motion for which the resolution was an enabling act

*The Vice-Speaker* All those in favor of the appointment of Dr Britt on this Special Committee?

Motion seconded and carried

### 40 REFERENCE COMMITTEE ON REPORT OF SPECIAL COMMITTEE ON NURSES

(Report in May 1 JOURNAL, page 470)

*Dr Jewett* Reference Committee on Report of Special Committee of Nurses endorses the following recommendations

1 The establishment of official nurses' registries in every county of this State.

2 That every county society develop plans for the official approval of registries which meet satisfactory standards to be erected by the county society

3 Sincere efforts toward co-ordination of all nursing services in each county

could do so and we would not have to have a rush meeting

I move the adoption of the amendment. Seconded and carried

#### 59 EXPENSES OF DISTRICT BRANCHES

*The Secretary* The next is to amend Section 45—"Be amended as to \$100 per annum being insufficient for the District Branches"

Now that is very indefinite in its wording. It is not really in the shape of an amendment, and I move, Mr Speaker, that that be referred to the Committee on Revision of Constitution and By-Laws—that will be appointed by the President. There has already, of course, been a reference to it in the President's report, and that was referred, so I move that this amendment be referred to the committee on revision of Constitution and By-Laws

The Speaker thinks that perhaps we ought to pass this so that it would be a little elastic for this year, and we might allow them more than a hundred dollars, but I think, Mr Speaker, the wording should be different.

*Dr Kopetzky* The appropriation of moneys is in the hands of the Trustees, as I understand.

*The Speaker* We have a limit of \$100 as provided in Section 45 of the By-Laws. That limit should be removed in the interest of the District Branches. Amendment to Section 45 strike out the words "Not to exceed one hundred dollars per annum"

*Dr Kopetzky* We are satisfied with that.

*The Secretary* I move the adoption. Seconded and carried (Sec 48)

#### 60 COMMITTEE ON LEGISLATION, RESTRICTIONS ON

*The Secretary* The next amendment was an amendment to Section 54, but that was erroneous because in the meantime it was taken from our old by-laws, the section became 57. So it is an amendment to Section 57 "Committee on Legislation." Following the last line, add the words "It shall not present to the Legislature of New York State or sponsor legislation affecting medical practice until approved by the House of Delegates"

*A Delegate* I move the adoption. Seconded.

The Secretary read a letter from Dr Shaw to the House of Delegates, giving reasons why this amendment should not be adopted.

*Dr Chalmers* I want to endorse heartily all that has been said in Dr Shaw's letter. It seems to me it would be suicidal to require that any legislation to be endorsed by the Legislative Committee should first have the endorsement of this House. The House is not in session except once a year. It has an Executive Committee and Council. It seems to me that to pass this resolution would simply mean you hamper your legislative committee.

*The Vice-Speaker* If there is no further discussion, those in favor of adopting this amendment say Aye. Opposed No. It is lost. (Sec 44)

#### 61 DISTRICT BRANCH BOUNDARIES

*The Secretary* Now, there is an amendment to the Constitution Article XI District Branches

It redistricts the branches by changing the counties in the different branches

First District shall include the Counties of Bronx, Dutchess, New York, Putnam, Rockland, Sullivan, Ulster, Westchester

Second District shall include the Counties of Kings, Nassau, Queens, Richmond, Suffolk

Third District shall include the Counties of Albany, Columbia, Greene, Montgomery, Rensselaer, Schenectady, Schoharie

Fourth District shall include the Counties of Clinton, Essex, Franklin, Fulton, Hamilton, Saratoga, Warren, Washington

Fifth District shall include the Counties of Herkimer, Jefferson, Lewis, Madison, Onondaga, Oneida, Oswego, St. Lawrence.

Sixth District shall include the Counties of Broome, Chemung, Chenango, Cortland, Delaware, Otsego, Tioga, Tompkins

Seventh District shall include the Counties of Cayuga, Livingston, Monroe, Ontario, Schuyler, Seneca, Steuben, Wayne, Yates

Eighth District shall include the Counties of Allegany, Cattaraugus, Chautauqua, Erie, Genesee, Niagara, Orleans, Wyoming

There is an objection in the report of the Sixth District Branch. It says that if passed as proposed it would take Schuyler and Steuben from the Sixth District. Both counties object to this change and prefer to remain in the Sixth District, and there is a letter from the Secretary of Steuben County saying some of the members of the County Medical Society would like to have the County Medical Society included in the Seventh instead of the Sixth.

*The Vice-Speaker* Do you desire to move the adoption of these?

*The Secretary* I move the adoption in order to bring it before the House.

Seconded

*Dr Schiff, Clinton* On behalf of the Fourth District Branch, on the part of the counties representing this branch, we believe it is extremely unfair to the Fourth District. It removes the only populous counties in our district and attaches them to a populous district, the Counties of Montgomery and Schenectady, and would leave the Fourth District with almost entirely a rural population, a rural territory, only Glens Falls and Plattsburg having the status of cities. Considering that fact and the objection already registered in the Report of the Council of the Sixth District Branch, it is my belief this should not be passed, and, Mr Speaker, I would move, if I am in order, that this redistricting amendment of the Constitution be referred to the committee which has already been provided for in regard to revision of the Constitution and By-Laws. I would say further that to my knowledge the proposition that involved our district was not put up to the District Branch as a whole, nor to the County Society, and I believe that when this redistricting is done a personal communication from the committee in charge of it to each county society involved at least, should be made. I therefore— if that is an amendment, if I am in order, move that it be referred to the Committee on Revision of the Constitution and By-Laws and they communicate with the counties

*The Secretary* I accept the amendment.

*A Delegate* I move the amendment.

Seconded.

*The Vice-Speaker* The motion as it stands now is that these changes be referred to the new committee on Revision of Constitution and By-Laws

Seconded and carried.

#### 62 A. M. A. COMMUNICATION ON ALCOHOL AND NARCOTICS

*The Secretary* I have a communication from the American Medical Association in regard to the needed safeguards in the promulgation of regulations under the National Prohibition Act and the Harrison Narcotic Act. I move the adoption of these resolutions

Seconded.

*The Vice-Speaker* The regular order of business would require reference of this resolution to a reference committee. If it meets with the approval of the House we will abolish such reference and discuss it in open meeting

*Dr Phillips* I so move.

Seconded

*The Vice-Speaker* Is there any further discussion?

quently confer with his executive officers and the Presidents of the component County Societies in advancing the interests of the component County Societies and their respective district branches

I move the adoption Seconded and carried

#### 48 EXPENSES OF DISTRICT BRANCHES

*Dr Hicks* 4 Your committee urges the adoption of the constitutional amendment deleting the one hundred dollar appropriation for District Branch Annual meetings and recommends the amount of such appropriation be left to the judgment of the trustees

*The Vice-Speaker* That is out (Sec 59)

#### 49 GRADUATE INSTRUCTION

*Dr Hicks* 5 We endorse the sentiments of the President concerning County Society Post Graduate Instruction and the operation of the Medical Practice Act

I move the adoption Seconded and carried. (Sec 29)

#### 50 COUNTY COMMITTEES ON PUBLIC RELATIONS

*Dr Hicks* 6 We endorse the recommendations of the President that each County Society appoint a committee known as the Committee on Public Relations unless such committee already exists and that another standing committee on Public Relations be created in the State Society (Sec 32)

I move the adoption Seconded and carried

#### 51 HEART COMMITTEE

*Dr Hicks* 7 We recommend that the Heart Committee be authorized to continue the work for another year (Sec 31)

I move the adoption Seconded and carried

#### 52 TRI-STATE CONFERENCE

*Dr Hicks* 8. Concerning the 'Tri-State Conference,' your committee endorses the recommendations of the President.

I move the adoption Seconded and carried

#### 53 CONFERENCE OF COUNTY SECRETARIES

*Dr Hicks* 9 Your committee heartily endorses the suggestion that the executive officer call a conference of the secretaries of the County Societies annually

*The Secretary* I would like to know why the executive officer should usurp the office of the secretary The President says here he merely suggests, and most of these you will notice in Dr Fisher's report that you are adopting as recommendations, are not recommendations, they are suggestions Dr Fisher does not want to make positive recommendations of this kind, knowing that if he asked that a recommendation be adopted we would out of sympathy and courtesy and fraternal friendship pass the motion But here it says the executive committee authorizes the secretary and the executive officer Of course the secretary has charge of those matters and the executive officer works with him This is merely a suggestion and is not a recommendation and I do not think it should be in the report.

*The Vice-Speaker* It is always done anyway

*Dr Hicks* Shall we leave that out?

*The Vice-Speaker* Yes, leave that out.

*Dr Hicks* Number 9 is eliminated

#### 54 NEW YORK STATE JOURNAL OF MEDICINE

10 Your committee joins the president in congratulating the State Society on the improvements noted in the NEW YORK STATE JOURNAL OF MEDICINE.

I move the adoption Seconded and carried.

#### 55 PRESIDENT'S EXPENSES

*Dr Hicks* 11 Your committee is convinced that the expense allowance of the President of the State Society is totally inadequate and should be increased.

The Committee did not make any definite recommenda-

tion as to that It leaves it up to the House of Delegates

*Dr Fisher* I might say that is only a suggestion. Personally it does not make a bit of difference to me. But you may run against a president who cannot see his way clear to take the interest which the State Society would like to have I do not think it is an exorbitant amount that is required The per diem is ten dollars and railroad expenses Those of you who have traveled any know in these days ten dollars will not pay the expenses of a man traveling first class, and in fact this is part of your By-Laws, and for that reason I would suggest that you approve the report and refer it to the new committee on Revision of the Constitution and By-Laws

I move that this matter be referred to the Council

Seconded and carried

#### 56 DEATHS OF PAST PRESIDENTS CAMPBELL AND JONES

*Dr Hicks* 12 Your committee joins the President in his expressions of sorrow in the deaths of Dr Owen Elon Jones and Dr William Francis Campbell and wishes to emphasize the great loss this society has sustained in the deaths of these two ex-presidents

I move the adoption Seconded and carried. (Sec. 2)

#### 57 COMMENDATION OF PRESIDENT FISHER

*Dr Hicks* Your committee wishes to express great satisfaction for the able manner in which the President has conducted the affairs of the society during the past year and feels that the society is to be congratulated on his devotion to the Society's interests at great personal sacrifice

I move the adoption Seconded and carried.

Upon motion, duly seconded and carried, the meeting adjourned to reconvene at eight o'clock in the evening

#### EVENING SESSION, MONDAY, MAY 9TH, 1927

The meeting was called to order by the Vice-Speaker at 8 45 o'clock P M

*The Vice-Speaker* Is there any reference committee that has not reported? If there is none, the next order of business is unfinished business Is there any unfinished business, Mr Secretary?

*The Secretary* The amendments to the By-Laws

#### 58 AMENDMENTS TO THE BY-LAWS ELECTION OF A. M. A. DELEGATES

The first amendment, Mr Speaker, is the amendment to Section 17—Second line, after the word "elected" insert the words "in the calendar year preceding the meeting of the House of Delegates to which they are elected"

That, Mr Speaker and gentlemen, was offered as an amendment in order to obviate such a condition as we find ourselves in tonight. We have tomorrow morning to elect seven delegates to the House of Delegates of the A. M. A., which meets next Monday, and according to their by-laws we should have had the names of those delegates in Dr West's possession three days ago I saw Dr West in Chicago and he said if we telegraphed them immediately in the morning after election it would be all right, but of course they are not printed in the bulletin of the little handbook of the A. M. A. that is given to the delegates This amendment will allow us to elect our delegates tomorrow and then elect the second class What I mean to say is, tomorrow, in the usual order of things—I am taking the place of the Speaker in explaining this because he has asked me to use my voice instead of his—we elect tomorrow the men for 1927-1928 By passing this amendment it would allow us to vote also for those for 1928-1929 In that way this House of Delegates could meet any time in the year that it wished, irrespective of the A. M. A.'s House of Delegates meeting We would always be a year ahead and if we wanted to meet in July or June we

I therefore move that this election be referred to the Council Seconded and carried

The following were elected delegates to the American Medical Association for the years 1927-1928

Dr Thomas C. Chalmers,  
Dr George M. Fisher,  
Dr Arthur J. Bedell,  
Dr Grant C. Madill  
Dr Arthur W. Booth,  
Dr Frederick H. Flaherty  
Dr Edward L. Hunt.

The following were elected alternates to the American Medical Association for the years 1927-1928

Dr Frank D. Jennings,  
Dr Samuel J. Kopetzky,  
Dr Arthur G. Bennett,  
Dr Martin B. Tinker,  
Dr Floyd Winslow  
Dr Charles G. Heyd  
Dr Andrew Sloan

The following were elected delegates to the American Medical Association for the years 1928-1929

Dr James N. Vander Veer,  
Dr E. Eliot Harris,  
Dr Nathan B. Van Etten,  
Dr George A. Leitner,  
Dr Daniel S. Dougherty  
Dr Orrin S. Wightman  
Dr J. Richard Kevin

The following were elected alternates to the American Medical Association for the years 1928-1929

Dr John E. Jennings,  
Dr Edward R. Cunniffe.  
Dr George W. Cottis,  
Dr Edwin A. Griffin,  
Dr Edward W. Weber,  
Dr Albert W. Ferris,  
Dr David E. Hoag

## 66 PRIZE ESSAY

The following report was presented by the Committee on Prize Essays

Comparatively few essays have been offered to our Society in Competition for the Lucien Howe prize in ophthalmology. Only after the lapse of several years has any been deemed worthy of the award. But this year one of unusual merit has been sent to the Committee. It is entitled *Photography of the Fundus Oculi*. It reviews methods adopted by earlier investigators, gives photographs of the varieties of apparatus formerly employed and then the plan adopted by the writer. He gives also a number of plates, including over a hundred photographs of the fundus oculi, in a normal and abnormal condition.

Many other details of excellence might be described, but for this report it must suffice to say that the essay referred to is a piece of work which reflects great credit on the patient, exact, scientific work of some member of the Medical Society of the State of New York and our prize in ophthalmology is therefore, awarded to the author of this Essay signed "Retina."

LUCIEN HOWE, *Chairman*

The envelope marked "Retina" was then opened and the Speaker called on Dr Arthur J. Bedell, whose card was enclosed, and presented him with a gold medal as the winner of the Lucien Howe Prize.

## 67 THANKS TO COMMITTEE ON ARRANGEMENTS

*The Vice-Speaker* I would suggest that we appropriate this time to extending a vote of thanks to the members of the Committee on Arrangements and the Chamber of Commerce to whose work this splendid meeting is due. I move the adoption of this resolution. Seconded and carried.

There being no further business, the meeting adjourned.

E. ELIOT HARRIS, *Speaker*  
HARRY R. TRICK, *Vice-Speaker*,  
DANIEL S. DOUGHERTY, *Secretary*

Carried

### 63 INVITATION FROM THE MAYOR OF TORONTO

*The Secretary* I have a communication from the Mayor of Toronto, and with your permission, I don't believe it is necessary to read it. The Mayor invites the delegates to visit Toronto and tells you what you can see there.

*The Vice-Speaker* This does not require any formal action. If there is no other business to come before the House, a motion to adjourn will be in order.

*Dr Kopetsky* I move you, sir, we adjourn to reconvene to-morrow morning at 9 30.

*Dr Hubbard* Before we adjourn, we have a very distinguished gentleman from Albany with us, and I would like to have a few words on the Medical Practice Act from Dr Augustus Downing.

*Dr Downing* addressed the meeting.

*Dr Kopetsky* I move this House of Delegates extend our heartfelt thanks to Dr Downing for his efforts in helping us to the Medical Practice Act and our good wishes for his future. Seconded and carried.

*The Vice-Speaker* There is a motion before the House. Will you state your motion again, Dr Kopetsky?

*Dr Kopetsky* I move we adjourn to reassemble for regular business at 9 30 tomorrow morning.

The meeting then adjourned to reconvene Tuesday morning at 9 30 o'clock.

### ADJOURNED SESSION OF THE HOUSE OF DELEGATES

Tuesday, May 10, 1927

The meeting was called to order by the Speaker at 9 30 A M.

### 64 ROLL CALL

*The Speaker* The Secretary will call the roll.

The Secretary called the roll and the following delegates responded:

Arthur J Bedell, William P Howard, Thomas W Jenkins, Chauncey R Bowen, Nathan B Van Etten, Edward R Cuniffe, Cornelius J Egan, Vincent S Hayward, Isidore J Landsman, Edward C Podvin, Clarence Smith, Edmund E Specht, Frank M Dyer, George S Lape, Edgar Bieber, George W Cottis, Reeve B Howland, George D Johnson, Leo F Schiff, Charles L Nichols, R. Paul Higgins, C. Knight Deyo, William A Krieger, Aaron Sobel, W Warren Britt, Russell Wilcox, George R Critchlow, Robert De Ceu, H P Hourigan, Baldwin Mann, Charles L Davis, Alton B Daley, Arthur W Albones, Norman L Hawkins, Elias H Bartley, Thomas M Brennan, George A Clark, Roger Durham, Charles H Goodrich, Edwin A Griffin, Ralph F Harloe, John E Jennings, William A Jewett, J Richard Kevin, Howard T Langworthy, Carl H Laws, Walter D Ludlum, Joseph W Malone, John J Masterson, William C Meagher, Binford Throne, Charles E Scofield, Alec N Thomson, Emil Goetsch, Harvey W Humphrey, Samuel H Raymond, Charles R Barber, James P Brady, Joseph P Henry, Willard H Veeder, Floyd S Winslow, Horace M Hicks, Gustave A Fensterer, Louis A Van Kleeck, Milton A. Bridges, C Ward Crampton, John Douglas, Walter T Dannreuther, Robert H Halsey, David E Hoag, Ward B Hoag, S Dana Hubbard, Peter Irving, David J Kaliski, Henry Keller, Meyer Robinson, Lawrence K. McCafferty, J Milton Mabbott, Henry S Patterson, William M Patterson, James Pedersen, Malcolm C. Rose, Mary D Rose, Frederic E Sondern, Terry M Townsend, Louis Tulipan, Lazarus W Zwisohn, Frank Guillemont, Frederick J Schnell, Andrew Sloan, Thomas P Farmer, Albert G Swift, Frederick S Wetherell, Homer J Knickerbocker, Joseph B Hulett, Frank E. Fox, Ray D Champlin, Carl Boettiger,

Thomas C Chalmers, Henry C. Courten, L. Howard Moss, Ernest E Smith, Arthur G Whelan, James H Flynn, John H Reid, Enrico C Soldini, George A Leitner, W Grant Cooper, Carl R Comstock, Stillman S Ham, Dudley R Kathan, Albert W Ferris, Robert M Elliott, Leon M Kysor, Herbert B Smith, William H Ross, Frank Overton, Luther C Payne, A Max Fisher, Luzerne Coville, Frank L Eastman, Morris Maslon, Lucius H Smith, William H Cantle, Harrison Betts, George B Stanwix, Ralph T Todd, Edward W Weber, William R. Thomson, Le Grand A. Damon, Fred G Jones, Howard D MacFarland.

The following officers, trustees, and chairman of standing committees were present:

George M Fisher, James E Sadlier, E. Eliot Harris, Harry R. Trick, John E Jennings, George M Cady, Daniel S Dougherty, Howard Gillespie Myers, Charles Gordon Heyd, James Pedersen, John A. Card, Joseph S Thomas, Charles P McCabe, Horace M Hicks, Charles D Post, Claude C Lytle, George W Cottis, Samuel J Kopetzky, Frederick J Schnell, W Warren Britt, Frederick H Flaherty, Nathan B Van Etten, Grant C Madill, William H Ross, Arthur W Booth.

The following ex-presidents and ex-secretary were present:

Charles Stover, Wendell C Phillips, Grant C Madill, J Richard Kevin, Arthur W Booth, Orrin Sage Wightman, Nathan B Van Etten, Edward Livingston Hunt.

*The Speaker* A quorum is present. I will now call upon the President to introduce the President of the American Medical Association, Dr Phillips.

Dr Phillips addressed the House.

*The Speaker* I shall ask the President of the Society to introduce Dr William Allen Pusey, ex-President of the American Medical Association.

Dr Fisher introduced Dr Pusey who addressed the House.

### 65 ELECTION OF OFFICERS

*The Speaker* Preliminary to the election of officers. Chairmen of Committees and delegates to the American Medical Association, a few statements will be made by the Secretary.

*The Secretary* First, Mr Speaker and gentlemen, I would like to state that Dr Meyer Robinson has been substituted for Dr George W Kosmak in the delegation of the County of New York.

The tellers will be as follows:

Table 1	Luzerne Coville
	William M Patterson
	George R. Critchlow
Table 2	John E Jennings
	Carl Comstock
	George M Cady

*The Secretary* I move that nomination speeches be limited to two minutes. Seconded and carried.

The following officers were nominated and declared elected:

President Elect Dr Harry R Trick, Speaker, Dr E Eliot Harris, Vice-Speaker, Dr John A. Card, First Vice-President, Dr Joshua M. Van Cott, Second Vice-President, Dr Horace M Hicks, Secretary, Dr Daniel S Dougherty, Assistant Secretary, Dr Peter Irving, Treasurer, Dr Charles Gordon Heyd, Assistant Treasurer, Dr James Pedersen, Trustee, Dr James F. Rooney, Chairman Committee on Scientific Work, Dr Samuel J Kopetzky, Chairman, Committee on Public Health and Medical Education, Dr Thomas P Farmer, Chairman, Committee on Legislation, Dr Henry L K Shaw, Chairman, Committee on Medical Economics, Dr W Warren Britt.

*The Secretary* With regard to the election of the Chairman of the Committee on Arrangements, it has been the custom for years to lay this over until we know where the next Annual Meeting will be held.

sion to educate the public in medical matters, and reiterated the broad views which he set forth in his inaugural address which was published in the May 1, 1926, issue of this JOURNAL, and which were heartily approved by the medical profession of New York State

The subject of medical publicity aroused considerable discussion which was given wide notice in the daily press. The conclusion was that medical publicity and education was desirable if it was conducted under the authority and censorship of a medical society

The discussion of medical publicity has some inconsistent features. The question has not aroused contention in New York State, but on the contrary, New York physicians in private practice and in departments of health discuss medical problems freely in the newspapers and magazines. The New York State doctors would not permit the insertion of the cards of surgeons and other specialists in their medical journals, and yet the official medical journals of some state societies in the Middle West, where the leading critics of medical publication live, carry whole pages of the paid advertisements of specialists, and no one seems to make objection to the practice. These things are regulated by local custom

The question of publicity came up in another form during the discussion of periodic examinations. It was felt by some that physicians would be acting unethically if they solicited the examinations, and therefore a resolution was introduced and adopted that the A M A prepare a form letter which would be distributed to physicians through the county medical societies. This letter would call attention to the benefits of having the examinations made by family physicians and records kept for the benefit of the patients only

Dr Phillips discussed the conference on Public Health which was held in Chicago on the 24th and 25th of last March and was reported in this JOURNAL in the April 15, 1927, issue. The recommendation that a similar conference be held annually was approved

The subject of legal restrictions on prescriptions for alcoholic liquors was discussed by Dr Phillips, and was considered by the House at length in executive session. The Reference Committee finally reported as follows

"As regards the purport of the resolution presented by the Medical Society of the State of New York in relation to medicinal alcohol, stripped of all verbiage, this resolution demands that the principle here promulgated takes the issue out of all wet or dry questions and insists that the physician be given by Congress the freedom from restriction to prescribe alcohol in disease as his scientific judgment dictates. We therefore offer the following resolution

*"Resolved,* That the American Medical Association declares its adherence to the principle that legislative bodies composed of laymen should

not enact restrictive laws regulating the administration of any therapeutic agent by physicians legally qualified to practice medicine.

"The above resolution states succinctly the principles involved and the result desired therefrom. The question therefore arises, How may this result be best brought about? It has been suggested through the following resolutions offered in the House of Delegates by Dr Chalmers that a referendum be taken regarding this opinion on therapeutic use of alcohol in disease and that the results of this referendum be offered to Congress

*"Resolved,* That the trustees of the American Medical Association be requested to send to every registered physician practicing in the United States a ballot requesting him to vote on the following question.

"Are alcohol and alcoholic liquors, as listed in the latest edition of the United States Pharmacopeia, useful therapeutic agents in the treatment of disease?"

"And be it further

*"Resolved,* That the trustees of the American Medical Association be requested to submit the returns of this questionnaire in a memorial to Congress, asking that the restrictions on the quantity of alcohol and alcoholic liquors that may be prescribed for the sick be removed

"With reference to the resolutions of Dr Chalmers of New York suggesting a referendum, your committee would recommend that this matter be referred to the Board of Trustees with power to act. In the event that a referendum is considered advisable, your committee would suggest the following questions

"(a) Do you believe that legislative bodies should enact laws regulating or limiting the prescribing of therapeutic agents by legally qualified physicians?

"(b) Do you believe that alcohol and alcoholic liquors as listed in the latest edition of the United States Pharmacopeia are useful therapeutic agents in the treatment of disease?"

The resolutions were adopted

The Reference Committee on Hygiene and Public Health made a supplementary report on the relations between medical men and health officers, and began by saying

"The question involved is. Is it or is it not one of the essentials of ethical practice of medicine that the practitioner of medicine become, in his local area, a quasi, unpaid assistant to the department of health?"

That question has never been definitely answered

That question has been answered definitely in New York State, and a close cooperation has been going on for several years between the health departments and family physicians. The culmination of the cooperation came with the

# NEWS NOTES

## THE AMERICAN MEDICAL ASSOCIATION

A careful reading of the reports of the proceedings of the meeting of the American Medical Association as set forth in three sources, 1, the handbook provided for the information of the members of the House of Delegates, 2, the current reports in the daily press, and 3, the minutes published in the *A M A Journals* of May 21 and 28, and June 4, justifies the conclusion that the meeting was exceedingly fruitful in diagnoses, prognoses, and therapeutics in practically all the fields of activity which engage the attention of the modern physician, and which will demand a more intensive consideration by physicians in the immediate future. The officers and committeemen of the *A M A* have given deep consideration to the civic duties of physicians throughout the Nation. This article will review some of the more salient features of the meeting.

The preparation of a synopsis of the convention proceedings to be sent to the State journals was authorized by the adoption of a motion to that effect introduced by Dr O. S. Wightman, Editor-in-Chief of the *NEW YORK STATE JOURNAL OF MEDICINE*. But since the proceedings of the House of Delegates are "Live" news, it has seemed best that this *JOURNAL* should report the proceedings before the synopsis is received.

The examination of the minutes printed in the three issues of the *A M A Journal* and the determination of the actions taken on the reports and resolutions would have been greatly facilitated if the paragraphs of the minutes had been numbered and cross referenced as is done with the minutes of the New York State House of Delegates published on page 670 of this issue of this *JOURNAL*.

The meeting of the House of Delegates opened with reports of the Speaker, Dr F. C. Warnshuis, the President, Dr Wendell C. Phillips, and the President-elect, Dr Jabez N. Jackson. These reports were based on the activities of the Association during the past year, and contained suggestions for the ensuing year.

The Speaker's address covered three principal points:

1. A commendation of the appointment of reference committees thirty days in advance of the Annual Meeting. This suggestion had been carried out for the meetings of 1926 and 1927, and on a motion seconded by Dr Bedell of New York, the principle was approved. The action of the Medical Society of the State of New York in electing its delegates a year instead of a week in advance of the meeting should result in a wider

inclusion of representatives from New York on the committees.

The Speaker discussed the publication of the reports of the officers and committees in the *JOURNAL* a month before the meeting. There was some discussion of the advisability of deferring the publication of the reports of the officers and committees before they had been considered by the reference committees. The reference committee had recommended as follows:

"Future reference committees should have the opportunity of passing on addresses referred to them before they are given publicity either in the *JOURNAL* or in public print. The reason for this recommendation is obvious for reasons of policy, for in this way only may these reports go forth with the added authority of the House of Delegates."

However, this suggestion of the reference committee was not approved by the House.

This publication of the reports of officers and committees before the Annual Meeting has been adopted in New York and other states, and has promoted an increased interest in state and national medical affairs by both the delegates and the members generally. Wider publicity of medical society affairs is a progressive step in medical administration.

2. The Speaker referred to the existence of two committees on nursing. Their reports on nursing were voluminous and exhaustive, and while few conclusions were presented, the continuance of the investigations was approved.

The Board of Trustees suggested the appropriation of \$5,000 to continue the study of the nursing situation, and the suggestion was approved by the House.

Dr N. B. Van Etten is Chairman of the Nursing Committee of both the New York State Society and the *A M A*. The physicians of New York State favor a more intensive study of the nursing problem and the development of agreements with nursing associations and hospitals. The situation can best be clarified by the concerted action of all parties concerned.

3. Dr Warnshuis suggested that the *A M A* should appoint a committee of seven to consider the standards by which a medical practitioner should be recognized as a properly qualified surgeon. The suggestion was adopted. No reference seems to have been made to the work of standardization by the American College of Surgeons.

Dr Wendell C. Phillips, in his President's Report, discussed the duty of the medical profes-

sion to educate the public in medical matters, and reiterated the broad views which he set forth in his inaugural address which was published in the May 1, 1926, issue of this JOURNAL, and which were heartily approved by the medical profession of New York State

The subject of medical publicity aroused considerable discussion which was given wide notice in the daily press. The conclusion was that medical publicity and education was desirable if it was conducted under the authority and censorship of a medical society

The discussion of medical publicity has some inconsistent features. The question has not aroused contention in New York State, but on the contrary, New York physicians in private practice and in departments of health discuss medical problems freely in the newspapers and magazines. The New York State doctors would not permit the insertion of the cards of surgeons and other specialists in their medical journals, and yet the official medical journals of some state societies in the Middle West, where the leading critics of medical publication live, carry whole pages of the paid advertisements of specialists, and no one seems to make objection to the practice. These things are regulated by local custom

2 The Speaker referred to the existence of two committees on nursing. Their reports on nursing were voluminous and exhaustive, and while few conclusions were presented, the continuance of the investigations was approved.

The Board of Trustees suggested the appropriation of \$5,000 to continue the study of the nursing situation, and the suggestion was approved by the House.

Dr N B Van Etten is Chairman of the Nursing Committee of both the New York State Society and the *A M A*. The physicians of New York State favor a more intensive study of the nursing problem and the development of agreements with nursing associations and hospitals. The situation can best be clarified by the concerted action of all parties concerned.

3 Dr Warnshuis suggested that the *A M A* should appoint a committee of seven to consider the standards by which a medical practitioner should be recognized as a properly qualified surgeon. The suggestion was adopted. No reference seems to have been made to the work of standardization by the American College of Surgeons.

Dr Wendell C Phillips, in his President's Report, discussed the duty of the medical profes-

# THE DAILY PRESS

## THE LAWYERS' GRIEVANCE COMMITTEE

The provision for a Grievance Committee that was written into the new Medical Practice Act of New York State was modelled after a similar committee of the lawyers of New York State. The *New York Sun* of May 13, commenting editorially on the work of the lawyers' committee, said

"In this association alone between May 1, 1926, and April 30, 1927, complaints numbering 1,490 against members were filed with the committee on grievances, 440 attorneys were accused of neglect or carelessness or collusion against the interests of their clients, 238 were accused of improper charges of fees, 216 of misappropriating money or property, thirty-nine of employing improper methods of obtaining retainer fees, forty-seven of using tac-

tics verging on blackmail, and eight being convicted of crime. The committee recommended eighteen cases to the executive committee for disciplinary action, eight attorneys were disbarred and one was suspended for a year.

"Most complaints are made by clients. Bar associations would be most useful to defrauded clients and most dangerous to crooked lawyers if, in addition to the machinery for examining legal evidence, they set up machinery to make reasonable inquiry to determine whether evidence of which clients are ignorant might not also be found."

If one may judge by the number of cases brought before their inspective Grievance Committee, the physicians are fully as moral and upright as their legal brethren.

## MAN'S WORST ENEMY

An editorial in the *New York Herald Tribune* of May 20 says that man's worst enemy is man himself. It was based on the tragedy of a Michigan school dynamited by an insane man, and said—

"The treachery was confined to a brain, to the distorted imagination of the insane. It is lesser falterings of minds that kill the thousands who die under the wheels of automobiles. Most of the other victims of machines are really the victims of man.

"Perhaps some day we shall stop marveling at man's inventions and discoveries long enough to recapture the ancient truth that man's mind and heart, his fidelity, his honor, his good sense, are

still the central facts of our universe, and that without them nothing is worth inventing or discovering or possessing."

The psychiatrists are now joining the clergy in preaching the unreliability of man, and yet it is the spirit of Americanism to ascribe moral perfection to every human being until the contrary is proved beyond a doubt. It is assumed, for example, that any person is capable of driving an automobile until he has showed himself incapable by a careless act. A psychiatrist would test a man's ability to operate an automobile before allowing him to drive. Legal permission to pilot an automobile should be on the same basis as a license to captain a steamboat or an airship.

## ANTIVIVISECTION

A wave of propagandum for antivivisection has recently swept through the daily press, although it was only a tiny ripple on an inside page. That is about all the promoters of the cult seem able to achieve, although when news is dull the newspapers welcome any subject that can be magnified into a mild thrill. Many of the articles were written on behalf of the dog only, and the authors were quite willing that cats and monkeys and guinea pigs should be sacrificed.

The *New York Herald Tribune* for March 13 said editorially

"When vivisection is to be defended it is unnecessary to urge, although it is true that such experiments may contribute directly to the conquest of this or that disease or to the saving of this or that human life. It is enough to urge,

which is equally true, that they may contribute to the further banishment of ignorance. If one dog gives his life to buy a fact, he has done more than most men can do to aid the world."

Another point which has been urged by the anti-vivisectionists is that the laboratories in which experiments are done on living animals be open to inspection by anti-vivisectionists. This point is answered in the *Herald Tribune* of March 12 in the following letter by Benjamin C. Gruenberg, Managing Director American Association for Medical Progress:

"On March 6 you printed a group of letters under the general caption 'Full Light on Vivisection,' in which are expressed demands that the humane societies have free access to experimental laboratories.

active functioning of the Committee on Public Relations through which harmony was secured in the trinity of public health workers—physicians, health officers, and lay organizations. The principle of the cooperation on the part of the physicians is that of "Every physician a health officer," set forth by Dr. George E. Vincent in an address given before the Annual Meeting of the Medical Society of the State of New York on May 13, 1925, and published in the June 1, 1925, issue of this JOURNAL.

The report of the Reference Committee continues

"Whatever may be the opinion of either party—the department of health or the local practitioner—the situation is to be faced and settled on a broad basis of mutual understanding, not by useless resistance of either party to the controversy.

"Health boards and health officers are established facts. The physician has his established position in society. Whether he will or not, he must accept the existing conditions, he cannot nor should he attempt to stop the progress of civilization, rather should he become an aide to the administration of the functions of the health officer, and by so doing enhance his value to his patients and his public, for in the end he will find that resistance is only a damage to his public and also to his reputation and usefulness, for the health officer cannot perform his function without the physician, nor in the end can the physician alone or the entire medical body stop the progress of the effort for better hygienic surroundings and better health, nor if he were successful in such an effort would he accomplish anything but destruction of his own reputation and his usefulness in his place of residence.

"If there were no other reasons than those set down in the article under consideration, it is a condition and not a theory that confronts the physician, and he would not improve his personal position in his local environment by unreasonable resistance, while he will improve his position only in collaboration in the administration of the local health officer.

"There is no other course to be taken than that of collaboration, and in that method of meeting the situation he will find his only path to safety and material betterment, nor can the medical

group of any locality expect to benefit in a material way."

The report was adopted.

The New York State Medical Society has gone a step further, and has acted on the principle that physicians should not merely follow and support the health officer, but should assume the leadership of public health and the practice of civic medicine.

A detailed study of relief for indigent physicians was presented state by state in a five-page report. The conclusion was that so few physicians were in want that there was no need for the A. M. A. to consider an organized effort of relief.

The subject of medical education was considered, some delegates being of the opinion that this course in the medical schools should be simplified and made more practical, and others believed that still more basic science should be taught.

Several matters of specific interest were considered and adopted, among them were the following:

- 1 The regulation of cosmetics
- 2 Legalizing contraception advice for the benefit of health
- 3 Regulations regarding the labelling of cans of lye and other caustics
- 4 Establishing laboratories by the U. S. P. H. S. for the study of health hazards in industry
- 5 Recommending the formation of Disaster Relief Committees by the several states and counties. The City of Utica has such an organization. See this JOURNAL August, 1924, page 814.
- 6 Fees for making out insurance blanks in cases of death and accidents
- 7 Heroin addiction
- 8 Veteran's bureau
- 9 Medical Practice in the District of Columbia
- 10 Income tax exemptions

The meeting of the American Medical Association was a remarkable demonstration of the harmony that exists among the 140,000 physicians of the United States. It is gratifying that New York State, with over ten per cent of the population of the nation and of its physicians, ranks high in the solution of practically all the questions that were considered by the national body.

# BOOK REVIEWS

**SURGICAL CLINICS OF NORTH AMERICA.** Volume 6, Number 1, February, 1926. (Philadelphia Number) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues) Cloth, \$16.00, paper, \$12.00

The Philadelphia number comprises a large group of contributions by the leading surgeons of that city. The work of Dr. Babcock stands out most prominently, not only on account of the almost endless variety of conditions treated, but particularly because of the fact that this eminent surgeon has demonstrated the possibility of carrying out so much of his operative work, almost exclusively under spinal anaesthesia. It is a remarkable record of over 20,000 operations in about 20 years, with a practicably negligible mortality. He describes his technique in the most minute detail, guarding against mishaps by every possible precaution, and by prompt and suitable treatment when complications arise, as they occasionally do. This undoubtedly accounts for his remarkable results.

**SURGICAL CLINICS OF NORTH AMERICA.** Volume 6, Number 2, April, 1926. (San Francisco Number) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues) Cloth, \$16.00, paper, \$12.00

The clinics in this issue are of an eminently practical character. They deal with conditions that are of everyday occurrence in the average operating-room performances. The presentations are clear, concise, and to the point, whether it be the treatment of a fractured patella, a hallux valgus, the surgery of the biliary system, epithelioma of the cervix or an inversion of the uterus. There is an excellent article on the dissection of the neck with very good illustrations that will commend itself to those interested in this branch of surgery.

**SURGICAL CLINICS OF NORTH AMERICA.** Volume 6, Number 3, June, 1926. (Lahey Clinic Number) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues) Cloth, \$16.00 net, paper, \$12.00 net.

This issue is designated as the Lahey Clinic number. As one would expect, a great deal of space is given to the discussion of thyroid disease in its various forms, but other topics, as gall-bladder disease, gastro-duodenal ulcer, and other abdominal conditions receive sufficient consideration.

The advantages of spinal anaesthesia and also of ethylene as an anaesthetic are discussed at considerable length. The article on the chronic cardiac as a surgical risk is a very timely one, and will be appreciated by every surgeon. The treatment of emboli of the peripheral vessels with the report of a number of cases subjected to operation is certainly interesting and instructive.

HERMAN SHANN

**REMINISCENCES.** By GEORGE HENRY FOX, A.M., M.D. Octavo of 248 pages, illustrated. New York, Medical Life Press, 1926. Cloth, \$3.50

Dr. Fox has written a very interesting volume of reminiscences covering his early life in Saratoga County, New York, (he was born in Ballston Spa in 1846), Schenectady and Painted Post, his college years at the University of Rochester, (class of 1867), his study of medicine at the University of Pennsylvania and as medical interne in Blockley Hospital, his medical studies and travels in Europe—Leipzig, Berlin, Vienna, Paris, London, Rome, etc., his early practice in New York City,

beginning in 1873, his college appointments, hospital and dispensary practice, military experiences—Civil War and World War, medico-legal experiences.

Incidentally, he mentions the names of men who were prominent in medical affairs twenty-five to fifty years ago. One chapter is devoted to a sketch of the late Dr. Henry G. Piffard, and another to the Fox family history and the "Society of the Descendants of Norman Fox."

The book is very delightful reading and will be especially interesting to those who were students at the College of Physicians and Surgeons between 1880 and 1907.

IRA O. TRACY

**PRINCIPLES AND PRACTICE OF CHEMOTHERAPY.** With Special Reference to the Specific and General Treatment of Syphilis. By JOHN A. KOLMER, M.D. Octavo of 1,105 pages, with 82 illustrations. Philadelphia and London, W. B. Saunders Company, [1926] Cloth, \$12.00

In his symposium on Chemotherapeutics, Dr. Kolmer is indeed to be acclaimed for the successful completion of a task which he by reason of his immense amount of research was well qualified to undertake and which task was assuredly far from a light one.

Since the brilliant work of Ehrlich and his co-workers, chemo-therapy has developed into a far more complex subject than was conceived by him. Complex chemical and physico-chemical forces are involved in the effects of a chemical agent on both the body cells and invading parasites, and the matter of a selective destruction of parasites in the tissues would appear to be one of chemical or physico-chemical interaction between the chemical agent and the protoplasmic constituents of the parasites, just as the specific immunological processes of the body are being gradually placed on the same basis.

While it is true that the brilliant successes of chemotherapeutics in spirochetal, protozoan and metazoan diseases has not been approximated in the bacterial infections, still modern contributions toward the local sterilization of tissues by chemical agents, as well as the occasional brilliant results of systemic sterilization as more recently reported by Young and others with mercurchrome and similar synthetics, leads one to the hope that it may not be long before the dream of Ehrlich of a "Therapie Sterilisans Magna" may be achieved.

The physician at large is rarely aware of the tremendous amount of work that is being constantly carried on by the laboratory man, mostly on leads that are far from definite and all in the hope that something tangible may be achieved.

A considerable part of this book is devoted to Syphilis, the subject being covered in a varied and thorough manner. Well taken indeed, is the plea of the author for standardization of technique in the Wassermann reaction since so much dependence (and wrongly) is being placed on this single link in the chain of diagnosis and prognosis of this disease by a majority of the profession. Too true, indeed, is the very considerable danger that may ensue from placing too much reliance upon negative Wassermann reactions as an index of permanence of cures since even a series of two or three negative reactions may not mean a permanent freedom from subsequent relapse.

To each chapter is appended a complete list of references so that one may follow up in detail any lead found personally of value.

The reviewer has no hesitation in recommending this

"You will be interested to know that such access is actually offered to authorized representatives of humane societies and, for that matter, to any one who has legitimate excuse for visiting research laboratories. Medical laboratories, including the animal rooms, are open to the public. After making a survey covering virtually all of the medical colleges and research institutes in the United States, the American Association for Medical Progress, a national lay organization, found that responsible visitors are welcome at all times and that several of the laboratory directors extend special invitations to officers of humane societies in order that these officials may, if they choose, observe for themselves the manner in which the animals are cared for and the conditions under which they are used for experimental purposes.

"A few of the laboratories, the reports show, prefer visitors who have seen an operation performed on human beings. 'Only in this way,' writes one of the directors, 'can visitors appreciate in any degree the similarity between the two

and the care taken against inflicting pain and avoiding infection.'

"Besides maintaining a policy which encourages inspection of laboratories by one who may be properly interested, these institutions have all adopted a set of rules governing the custody, care and use of laboratory animals. All operations must first be approved by the laboratory director, and all animals used must be rendered insensible to pain if the operation is likely to cause greater discomfort than that attending anaesthetization. Exceptions to the use of anaesthetics can be made by the director alone, and then only when anaesthesia would defeat the object of the experiment.

"In view of the actual conditions it seems eminently unfair for your correspondents to insinuate, by demanding 'the open door,' that the facts are quite otherwise and that the practices in these laboratories, with which none of the writers claims to be familiar, are of a kind that should arouse the reprehensions of right-thinking citizens."

### UNNECESSARY NOISES

The *New York Times* of May 31 comments editorially on the campaign of Dr Louis I Harris, Commissioner of Health of New York City, to soften the unnecessary noises of New York City, and says —

"Professor A. M. Low is coming to the United States in June to help to eliminate unnecessary noises in New York. He has scored successes in London. It is his opinion that 'noise kills many persons annually and shortens life by diminishing human resistance.'

"It would be a mistake to limit a campaign of noise reduction to doing away with steam-riveting

The field of reform includes the roar of elevated railways, the grinding of wheels on surface cars, the pandemonium of auto horns, the resonances of jazz 'palaces,' uncurbed excesses of the radio industry and slamming of cans by ashmen on their rounds at night.

"Victims should study the law of nuisances and invoke it in the courts."

A lawsuit would be more nerve-racking than the noise on which it was based. The American citizens will have to make up their minds to develop a nervous immunity to noises rather than to attempt the hopeless task of suppressing them.

### QUESTIONNAIRES

The *New York Times* for May 27 says editorially

"Thirty or forty years ago some of the most popular weekly journals in England begged their readers to ask them questions. The storehouse of information was then in the editorial offices. Today the tables are turned, and the man who buys a newspaper finds a column with the headline staring him in the face, 'How Much Do You Know?'

"This is certainly different from the old way. The newspaper proprietor of other days did not presume to ask questions, he answered them. At present it is the editor who calls upon the reader to stand and deliver whatever knowledge he may have in his pockets.

"The *Saturday Review* writer does not believe that this fad will last long. The reason he gives is that 'we love opinions and we hate knowledge.'

We are fond of discoursing to our fellows about subjects on which we could not possibly pass an examination paper."

Only an exceedingly small percentage of physicians are addicted to the habit of either asking or answering questions through the columns of their medical journals. Three or four years ago it was expected that an open forum would be an appreciated feature of the *NEW YORK STATE JOURNAL OF MEDICINE*, but the department died aborning. However, the *Journal of the American Medical Association* uses questions asked by correspondents as the bases for brief textbook discussions of simple problems in diagnosis and therapeutics after the style of the best question and answer columns of the *New York Sun* and other periodicals in the days when knowledge was sincerely desired.

The first chapter speaks of indications of the brain resulting from functional disorder—depression, Manic-depressive psychosis, etc. Some salient points are given concerning feelings, structural processes and treatment of the diseases mentioned, with a number of case records.

Chapter on Brain Injury and its Sequelae—this is a group of somewhat hard subjects which are especially interesting in relation to certain interpretations associated with post-traumatic personality of the soldier in World War I, and are conditions which at least have a somatic basis even when not related post-traumatically.

The last Chapter—Alcohol Disruptive Vaso-Cerebral Conditions—describes the type of lesions produced in the last chapter's category. Central disturbance in the cerebellum and in cerebellar cerebral cortex and cerebellar tracts.

The contents of this book indicate one of importance to the general practitioner, but are rather sketchy.

Each chapter has an admirable bibliography of some range which enhances the value of the monograph for those with time to delve deeper.

H. G. DUNHAM.

**THE SIGNIFICANCE OF THE PHYSICAL CONSTITUTION IN MENTAL DISEASE.** By F. L. WATKINSON and RICHARD E. HARRIS. Ontario of 76 pages. Illustrated. Baltimore: The Williams and Wilkins Company, 1926. Cloth \$2.50. *Monographs* Vol. XI.

The recognition of personality and body types, and the grouping of human beings under different classifications is not a modern effort. Wetherston and Hesketh, appreciating this, give a very comprehensive review and discussion of the work of various investigators in these fields.

The material used in their study consists of 65 male patients, classified in four diagnostic groups: manic depressive (19), Schizophrenic (25), organic (10) and psychopathic personality and psychoneurotic (II) reaction types. Kretschmer's classification of morphological types (asthenic, athletic, pyknic and dysplastic) are followed in the main by the authors. The influence of age and growth is emphasized as a source of error in various observations.

The work of Kretschmer, "Physique and Character" has been criticized on the ground that it is descriptive or impressionistic—by what the eye could see, rather than through measurements. However the authors, in their studies, making use of simple observation and exact measurements (anthropometry) having, themselves, devised a new anthropometric index, arrive at practically the same conclusions as Kretschmer. Their results with the index indicate that the schizophrenic reaction types are predominately associated with the asthenic, athletic or dysplastic habitus (high index value), and the manic depressive reaction types are related to the pyknic or pyknicoid habitus—a sub-type of the pyknic described by the authors (low index value).

They also conclude that the pyknic habitus predominates in the "syntrophic" group, the asthenic-athletic in the "Idiotrophic" group.

The terms "Idiotrophic" and "syntrophic" are coined by the authors to denote tendencies or affective attitudes in individuals, although they use these terms in their tabulations to indicate prepsychotic personality. Perhaps these terms may be more descriptive of the individual's affective attitude, but they can be correlated with Kretschmer's schizothymic and cyclothymic, Bleuler's schizoid and syntoid, and Jung's introvert and extrovert—terms used to denote personality types. One feels that already the terminology of psychiatry is burdensome and that soon one will be unable to see the tree because of the woods.

In the organic and psychopathic personality and psychoneurotic reaction types no conclusions are drawn. However in their tables they indicate a predominance of the pyknic habitus in the former group, the pyknic and

asthenic-athletic being about equal numbers in the latter. Only one of the 65 cases are definitely in a psychopathic personality, but many asthenic-athletic, schizophrenic subjects are made from those who state that they would probably become more psychotic.

Schematic diagrams of most cases are shown, showing types of habitus and a summary comparison of the system enables the reader to see the relation of the body habitus to the personality. It is a pity that the book is not a little more fully illustrated as a manual for the student and the general practitioner.

One feels that the anthropological relations to the body and mind are not given the prominence of a general correlation of body structure with mental types of behavior, either propensities or psychoses.

A. E. WATSON.

**MEAT AND DAIRY HYGIENE.** Prepared by the Division of the Sanitary Service of the United States Army. Compiled by CARROLL HARRIS of BAKERS, V.C. Ontario of 64 pages. Baltimore: The Williams and Wilkins Company, 1924. Cloth \$0.50.

This extensive work has to do mainly with the government veterinary inspection service of fish and shell foods and dairy products for consumption by the United States Army. It is quite specific as to details and is very largely of a rather highly technical nature yet is clearly expressed and readable language. It tells of the selection, slaughtering, handling, curing and preserving of cattle, calves, sheep, goats, swine, poultry, fish and other food producing animals and eggs, milk, ice cream, butter and cheese. No one person could quite be an expert in all of these products covering their origin, care and handling. Therefore, much of the text is made up of definitions and standards from various sources.

It should be a great guide to those in or coming up to the army veterinary service or Federal packing house inspection.

The volume treats of several subjects quite wide of the mark of sanitary inspection of food products such as the care, handling and curing of hides, the preparation of various pharmaceuticals, complete slaughter house details of inedible parts, the different cold storage systems, descriptions of ice making machines, the mining and refining of ordinary salt and the manufacture of tin plate.

There is very considerable repetition in the book. One gets tired of reading twice over for instance how to use a trier on hams and other meat products. *Pork products*—Army bacon is treated of under the title in no less than four different places and all paragraphs very much the same wording.

The national standards for production and handling of Certified Milk are given in full but it is unfortunate that the old standards of 1912 are quoted rather than the much revised standards of 1923.

HARRIS MOAK

**ANATOMY OF THE WOOD RAT.** Comparative Anatomy of the Subgenus of the American Wood Rat (Genus Neotoma). By A. BRAZIER HOWELL. Six of 225 pages illustrated. Baltimore: The Williams and Wilkins Company, 1926. Cloth, \$5.00. (Monographs of the American Society of Mammalogists, Number One.)

This volume represents the first publication in a series of monographs of the American Society of Mammalogists. It treats of the comparative anatomy of the subgenus of the American wood rat (genus Neotoma). The subject has been handled in a complete and thorough manner. The chapters on Myology and Osteology are the results from a long and detailed study of this animal. The author is to be complimented upon the excellent illustrations which have been prepared from his own drawings and are self-explanatory. This book is of great value to those interested in comparative anatomy and to research workers who may use this animal for experimental purposes.

O. C. P.

excellent work to the general medical man as well as to the laboratory worker, for a careful, painstaking study of the same will clarify many points that to the present have not been readily available in such accessible form

ALEXANDER AISMAN

**ADVISING THE TUBERCULOUS ABOUT EMPLOYMENT** By W I HAMILTON and T B KINER. 12mo of 171 pages Baltimore, The Williams & Wilkins Company, 1926 Cloth, \$2.00

This is a valuable treatise of no little importance, medically and economically in this work-a-day world of ours. Giving adequate and sensible advice to a restored tuberculosis patient regarding employment is a difficult and often delicate task, carrying with it a very definite responsibility. If it is to be of value there is required of the adviser not only a grasp of the medical problem involved but also of the economic one, together with something of an idea of the hazards incurred in the following of any of the many occupations developed by modern industry and commerce.

It is just such information that this little book gives in a conservative practical manner. The authors base this advice on thoroughly modern concepts of the disease, and they are to be congratulated. They have wisely relegated to the rubbish heap a number of old superstitions and fetishes which have helped in subjugating not only the average layman but also a large portion of the profession itself—as for instance, the need forever after of living in some special kind of climate, or the advisability of engaging in some "out door" occupation, etc.

It would very well pay every physician who assumes the responsibility of advising the tuberculous about employment to read this contribution through from cover to cover and thoroughly to digest it.

FOSTER MURRAY

**BIOLOGICAL RELATIONS OF OPTICALLY ISOMERIC SUBSTANCES** By ARTHUR R. CUSHNY, M.A., M.D. Octavo of 80 pages Baltimore, The Williams & Wilkins Company, 1926 Cloth, \$2.00 (The Johns Hopkins University, School of Medicine, The Charles E. Dohme Memorial Lectures, Third Course, 1925)

This book of eighty pages consists of some lectures delivered by the late Dr. Cushny under the Charles E. Dohme Foundation at Johns Hopkins University in 1925. The subject matter is technical and such as to appeal to the chemist and pharmacologist. The first part deals with the discovery and researches of Pasteur on the isomeric tartaric acids and the power of their solutions to rotate the plane of polarized light. He then follows the history of the discovery of other optically active substances and then their action on plant and animal tissues. This leads up to a study of their pharmacological and toxic action and the theories of their specific action in therapeutics.

E. H. B.

**CLINICAL APPLICATION OF SUNLIGHT AND ARTIFICIAL RADIATION** Including Their Physiological and Experimental Aspects with Special Reference to Tuberculosis By EDGAR MAYER, M.D. Octavo of 468 pages Baltimore, The Williams and Wilkins Company, 1926 Cloth, \$10.00

In this highly instructive volume Dr. Mayer has collected and very well presented a vast amount of research work on light and its clinical application. In addition to his own very extensive work he describes that of many contemporary workers in this rather new field. There are very interesting chapters devoted to the nature of light and its artificial production, its therapeutic uses and the results thereof. The physics of light and its chemical effects are very well presented. The historical sketch is interesting and makes us realize that light therapy, while not recognized as such, has been practiced for ages. Much of the data given is

repeated verbatim from the original writers, but as due credit is given this is not objectionable. The case reports and photographs are clear and interesting. The work as a whole forms a definite contribution to our knowledge of light therapy, and its careful perusal can be recommended to all interested in the subject.

JEROME WEISS

**MENTAL INVALIDS** Being the Morison Lectures delivered before the Royal College of Physicians of Edinburgh in June, 1925 By C C EASTERBROOK, M.A., M.D., F.R.C.P.E., Physician-Superintendent, Crichton Royal, Dumfries. Oliver and Boyd, Edinburgh, 1925. Price, \$5.00

In this book Easterbrook discusses some of the practical psychiatric problems which have specially engaged his attention during the past thirty years.

The discussion is presented in the form of three lectures, dealing with the body-mind relationship, clinical examination of those mentally ill, etiology, prevention, classification and treatment of mental diseases.

A very good review of Freudian principles is given, and although the author recognizes and appreciates their value in the field of psychiatry, and stresses the importance of the study and treatment of the individual as a whole, nevertheless he warns against the substitution of what he terms speculative, for a descriptive psychology.

According to the author a "nervous invalid" is a "mental invalid," and in the lecture, "Causation of Mental Diseases," he speaks of a "nervous constitution" as the predisposing factor. There are many interesting statements as to what is to be included under this term. A remark is made, "the average American is becoming distinctly more 'nervy'." One wonders.

In "The Classification of Mental Diseases," formulated by the author twenty years ago, psychoses are grouped as congenital, constitutional, organic, organicismal or "bodily," toxic and energetic. In most instances the reaction types can be identified with those of The American Psychiatric Association classification, but in some they cannot be correlated. For example, the author considers, epilepsy and chorea as psychoneuroses. He also suggests the term "delusio" indicating a reaction type (Delusional Condition Unfixed), grouped with the constitutional psychoses. One feels the need of a universal terminology and grouping of reaction types so that we may all speak the same language.

Constitutional psychoses, including manic-depressive psychoses, dementia praecox, psychoneuroses, etc., are considered by the author as "specifically diseases of the association areas of the cerebral cortex, especially the frontal, but also the parietal." One can say so far studies have brought to light no change in the brain distinctive of the constitutional or so-called functional psychoses.

He emphasizes early treatment in the mental diseases and many pertinent statements are made relative to the treatment of voluntary patients in mental hospitals, and open-air rest treatment of active psychoses. It is interesting to note that Easterbrook practiced endocrinotherapy from 1894-1900, and draws some very striking conclusions.

"Mental Invalids" is well presented and might be spoken of as "easy reading." Much of the material is old, some new—a linking of the past with the present. The reading of it is recommended to those who wish to add to their general knowledge of psychiatry.

A. E. WITZEL.

**THE FINER DIAGNOSIS OF ACUTE BRAIN INVOLVEMENTS, Inclusive of Syphilis and Brain Injury** By J. VICTOR HABERMAN, A.B., M.D. Octavo of 116 pages New York (1926), (Monograph Medical Journal and Record)

This monograph is clearly not designed to be an exhaustive discussion of the subjects included.

# Summer Diarrhea

The following formula is submitted as a means of preparing suitable nourishment in intestinal disturbances of infants usually referred to as summer diarrhea:

**Mellin's Food**

**Water** (boiled, then cooled)

**4 level tablespoonfuls**

**16 fluidounces**

This mixture contains proteins, carbohydrates and mineral salts in a form readily digestible and available for immediate assimilation.

The need for protein is well understood as is also the value of mineral salts, which play such an important part in all metabolic processes. Carbohydrates are a real necessity, for life cannot be long sustained on a carbohydrate-free diet. It should also be stated that the predominating carbohydrate in the above food mixture is maltose—which is particularly suitable in conditions where rapid assimilation is an outstanding factor.

*Above all is the satisfactory result from the use of this suggested nourishment, which is well supported by clinical evidence*

**Mellin's Food Company, 177 State Street, Boston, Mass.**

## Blood Chemistry

**FOR PROGNOSIS AND DIETETIC TREATMENT  
In Nephritis, Diabetes and Diseases of Metabolism**

SUGAR  
URIC ACID  
TOTAL NITROGEN

NON PROTEIN NITROGEN  
CHLORIDES  
CO<sub>2</sub> COMBINING POWER  
CALCIUM

UREA NITROGEN  
CREATININE  
CHOLESTEROL

No charge for taking specimen from patient in the laboratory Price list covering all laboratory tests and containers with directions for taking specimens sent upon request

*All reagents used in our blood chemistry are  
standardized and Folin's methods are employed*

## THE FLOOD CRISIS IN ARKANSAS

The May *Journal of the Arkansas Medical Society* has the following editorial comment on the flood conditions in the State

"Sanitary measures and preventive medical treatment after the recent floods have proven their incalculable value and doubtless saved many lives by averting epidemics. Our Health Officer Garrison, the members of the State Board of Health, and their efficient office force, have been busy night and day. Dr. Garrison, Secretary of the Board, has shown wonderful ability and energy in handling the situation, which has no precedent in any flood disaster in the memory of anybody living. In some camps there has been some sickness, but it is a tribute to the medical profession that no epidemic has been reported. The herding together of men, women and children, and with them in some instances, domestic animals, and uninvited wild animals, for days at a time on high spots before they could be rescued, with no sanitary equipment, insufficient food and water supplies, together with inevitable soil pollution, must have precipitated serious conditions, but for the prompt measures and the untiring efforts of the medical authorities

"The members of our profession gave the best that was in them, untiring and unselfishly, but exposed themselves unhesitatingly to danger, even to death. For example, Dr. DeClark of McGehee narrowly escaped drowning while answering a call when his boat was overturned. Had he not been a good swimmer, he must inevitably have been drowned as he had to swim quite a distance in the rapid current before he was rescued.

"In this connection, it is in order to note

the great work done at Little Rock by the Arkansas Water Company, and the men working under the direction of the officials, in preventing the inundation of the pumping station. Day and night they worked even at times when it seemed that the labor would prove futile, and a possible water famine was fortunately averted. What a water famine would have meant to the health of the city of Little Rock is almost unthinkable.

"The various health authorities deserve recognition for their excellent work and their untiring zeal and prompt preventive measures taken. Yet in their zeal and anxiety there has been some criticism of the fact that many applying for vaccination against typhoid who were well able to pay, were referred to the Free Clinics, already overworked, instead of to the family physicians.

"At one of the larger clinics in Little Rock, the physician in charge complained of the distance from the clinic he was compelled to park his car, due to the congestion of the pauper's automobiles. With this sole exception, there is no room for criticism of the splendid efforts of the local health officer.

Throughout the State members of the medical profession had a herculean task, such as never confronted them before over so large a territory and involving so many people. Just how unselfishly and with such self-sacrifice of their own comfort and well being, this great work was accomplished and the people spared epidemics in addition to the physical damage to property and crops, would make an epic which never can be adequately told."

## PUBLIC HEALTH WORK IN THE FLOOD AREA

Professor Ira V. Hiscock of the Department of Public Health of the Yale Medical School describes his experiences in the flood area in the following article printed in the May issue of the *Monthly Bulletin* of the New Haven Department of Health—EDITOR'S NOTE

"An urgent call for assistance in connection with the public health problems of the flood area resulted directly in the reporting of Dr. H. A. Lanpher, Epidemiologist of the Connecticut Department of Health, and myself at the Memphis Headquarters of the Red Cross. Here we were

told on Tuesday, May 3rd, that the most pressing problems were then in the State of Arkansas where the State Health Officer had requested immediate aid. After receiving our typhoid inoculations and smallpox vaccination, with a group of other health workers from North Carolina and the International Health Board, we proceeded at once to Little Rock. While awaiting our train, and through the courtesy of the Memphis City Health Officer, we visited the great refugee camp on the Memphis Fair Grounds and

(Continued on page 694)

There is an item of \$2,000 00 appropriated from the general treasury toward the expenses of the Journal, and at the end the balance shows that the expenses of the Journal are \$3,196 67 in excess of the revenues. Therefore the actual deficit is \$5,196 67

The financial statements of many of the State Medical Societies are obscure. The members would like to know where the societies stand financially, and if the information was given simply and fully there would be more interest shown in the society by both the officers and the great mass of members

### FOREIGN BODIES IN THE CORNEA

Dr Ray H Fisher, of Rigby, Idaho, has the following article in the April issue of Northwest Medicine, telling how to remove foreign bodies from the cornea—Editor's Note

"It is a common thing for patients to consult you with foreign bodies in the cornea. You will find the removal of these bodies listed as a separate and distinct operation in the fee schedules of the industrial accident board. When a patient gets something in his eye he hurries to get it out, especially if it is imbedded in the cornea. He has learned that he cannot get it out at home because the cornea is sensitive and the foreign body is small and hard to see or move. In the office the procedure is comparatively simple, provided you have good light and the patient is in good position.

"Fifteen dollars will buy a suitable specialist's goose neck lamp, which every medical man should have. This is important for the removal of these foreign bodies. Also if you can afford fifty dollars for a specialist's chair, it is worth far more than that, even to the country practitioner. The object is to have the patient in a semiprone position, at ease and so placed that you may bend over him. Cocaine is imperative. Instill a liberal amount of 4 per cent solution. If you desire to use a lid retractor to give free access to the corneal field, do so, but this procedure is usually not necessary.

"You are now ready to remove the foreign body. I assume that you have cleaned your hands well, for this is a surgical procedure of importance and responsibility and only aseptic technic should prevail, lest a traumatic corneal ulcer, the very thing we are hoping to avoid, will be the result. Many do not have a suitable instrument for this delicate piece of surgery. Nine-tenths of the eye-spuds and instruments sold for this purpose are useless and many of them are positively harmful. They are clumsy, too wide and too thick on

"To meet the emergency situation there have been organized in the various counties Citizens' Relief Committees, made up of the leading citizens of the community. In the counties of this district we are proceeding as rapidly as possible to perfect permanent health organizations with modern programs for the future by converting these committees into Citizens' Health Advisory Committees to the health officer. It is anticipated that through such organization public health work will advance more rapidly than heretofore.

"The work everywhere has been most enjoyable because of the high type of citizens engaged in committee work and their excellent spirit of cooperation."

## URINE EXAMINATIONS

The Long Island Medical Journal is running a series of practical short papers on Urological Topics by Dr N P Rathbun. The May issue contains the following article on Urine Examinations — Editor's Note

"I believe it is the custom of most doctors to have all of their urine examinations made at a laboratory. I think this is good practice because the busy practitioner has neither the time nor the equipment to make many of the quantitative tests such as urea and chlorides that are regularly made in the well-equipped laboratory.

"I submit, however, that if the practitioner will supplement this with frequent personal examination, requiring only the most rudimentary equipment, that he will be well repaid for his trouble, particularly if he has in mind that it is one of his functions to take the first step in a diagnosis of surgical as well as medical lesions of the urinary tract.

"Don't be content with boiling a few drams of urine in a test tube with and without the addition of a few drams of Fehlings solution. These tests are perfectly all right and they have a definite place, but they don't entirely fill the bill. Yet I'm afraid that this often constitutes the sum total of what is usually spoken of as an office examination.

"As a starter, a simple inspection of a freshly voided specimen may yield much valuable information. Freshly voided urine should be perfectly clear and mildly acid in reaction. Any departure from this demands an answer. I would suggest that the doctor acquire the habit of doing a two-glass urine test on all of his male patients. This simple test is based on the fact that the first gush of urine washes out the anterior urethra and that any abnormal elements contained in the first glass represent pathology in the an-

terior urethra, whereas the second glass voided after the automatic irrigation of the urethra represents urine as it exists in the bladder. In other words, it practically amounts to a simple way of getting a catheterized specimen from the male bladder. If such a test is employed on a given patient and we find the first glass slightly turbid and containing shreds, while the second glass is clear, we are obviously dealing with a chronic anterior urethritis. If such a patient submits a casual or A. M. mixed specimen to a laboratory the report will come back, among other things, 'trace of albumen, numerous pus cells,' perhaps even 'an occasional hyaline cast.' Not infrequently a diagnosis of nephritis is based upon such findings and I have known a number of perfectly good 'risks' who were rejected by insurance companies for the same reason. This is obviously a gross error and one easily avoided if the doctor 'did' his own urine.

"One of the most frequent causes of cloudy urine is phosphaturia. The cloud of course could appear in both glasses and the diagnosis is readily made with a few drops of any strong acid. A persistent cloudy second glass, if phosphates are excluded, is positive evidence of some surgical pathology in the upper urinary tract and demands further investigation. The contents of the second glass should be the portion selected for routine examination, which should include not only the routine boiling tests but the microscope as well. It takes only a moment, and let me say for the man who has gotten out of the habit of using a microscope, it is primary stuff and easily reacquired. A few casts, a few R. B. C., an occasional clump of pus cells, may suggest a more careful laboratory examination, including special stains, animal inoculation, etc., and be the first step toward an early diagnosis that might otherwise be easily missed."

(Continued from page 697)

the point and are often too rough. They will do nicely for a foreign body lying just on the corneal surface. However, for the imbedded body a fine pointed instrument is best, like a cystotome used in cataract operations.

"While standing over the patient have him move the eyeball until the foreign body is in the most accessible position. Then tell him to keep his vision fixed on the object he is looking at, and with the instrument directed toward the corneal margin and away from the pupil, lift the body out, doing as little damage to the cornea as possible. There are many deeply imbedded bodies which are difficult to remove and much trauma will be done to the cornea during the procedure. It may even become perforated, if the operator is not careful. That is why I say a good light, proper position for the patient and operator, sufficient cocaine and proper instrument are important.

"If you have had difficulty and can see you have caused quite a little abrasion to the cornea, regard the case as a potential traumatic ulcer and begin treatment at once. Instill atropine, 1 per cent solution. Always explain the effect of both cocaine and atropine to the

patient so he will not think he is going blind because of his failure temporarily to accommodate. Follow the atropine with 15 per cent. fresh argyrol solution and cover the eye with a hard eye shield. Do not use cotton and tape, as the eye needs rest and these only irritate. Use instead the shield of which the real hard kind is the only one of merit, its advantage being that it does not press upon the eye or limit its movements. This is one place where argyrol is of merit, i.e. in an acute or likely acute inflammation. It is of no value in most eye inflammations of a subacute or more chronic nature. Have the argyrol instilled every two hours for two or three days.

"By this time the danger of ulceration is usually over. The denuded corneal tissue is rapidly replaced and there are no untoward effects. The effect of the atropine has now worn off and vision is normal.

"For these apparently little jobs demand a decent fee. Dignify surgery, and do not be afraid to put a respectable premium on your training and skill. Remember this is a procedure the layman or the chiropractor cannot do. A hundred rubs on the back or the "back-side" by a chiropractor will not remove a foreign body from the cornea."

## Victor Service in Your State

THE Victor X-Ray Corporation has assumed a responsibility to the medical profession which does not end with developing and manufacturing X-Ray and Physical Therapy apparatus of the most approved type. It is a tenet of the Victor code that the operator of a Victor machine has the right to receive technical aid when he needs it.

So, a nation-wide Victor Service Department was organized years ago and direct branches established in the principal cities of the United States and Canada, where Victor trained men are always available. These men, by drawing on the facilities of the Engineering Service and Educational Departments at the home office, are equipped to render technical assistance that is appreciated by every user of Victor equipment.

Victor alone maintains so comprehensive a Service Organization

### VICTOR X-RAY CORPORATION

2012 Jackson Boulevard . Chicago, Illinois

New York—131 E 23rd Street

Rochester—809 Rochester Gas & Electric Bldg, 89 East Ave.

Many physicians feel that Victor quality, with Victor service, implies a price higher than they can afford. But they are happily surprised when shown this Victor 5" X Ray Unit, complete with Coolidge Tube for radiographic diagnosis, for \$725.00. The same high quality applies here as in any other Victor equipment.

## NEUROSURGERY IN THE NEWBORN AND CHILDREN\*

By WILLIAM SHARPE, M D, NEW YORK, N Y

**S**URGICAL conditions of the nervous system in the newborn and children may be listed in their order of frequency as follows. Acute brain injuries in children, intracranial hemorrhage in the newborn, brachial birth paralysis, hydrocephalus and spina bifida. Tumors of the brain occur much more frequently than of the spinal cord, but they are both rare conditions compared with the above lesions and will therefore be merely mentioned in this report.

1 *Acute Brain Injuries in Children*—In my series of cases, the automobile is the common cause of the cranial injury to the child playing in the street and the next most common cause is the falling of the child upon its head from a height of apparently trivial extent, usually two or three feet but upon a hard pavement or curb. Such bumps upon the head of a severity to produce unconsciousness and necessitating the child being placed in bed or being brought to the hospital are usually of the type designated as "concussion," with apparently no organic change in brain tissue, fracture of the skull may or may not be present. Upon admission to the hospital of a child having had a cranial injury, if shock is present, then the treatment should be directed toward this general condition of shock—typically a subnormal temperature and blood pressure but an increased pulse and respiration rate, extensive neurological examinations, roentgenograms, et cetera, should be postponed as they will not improve the condition of shock and all treatment should be directed toward overcoming the shock. If the patient can survive this condition of initial shock, then the routine neurological examinations, X-rays, ophthalmoscopic and spinal puncture tests, et cetera, can be performed to obtain an accurate opinion of the intracranial status.

The expectant palliative treatment of warmth, quiet, ice helmet, dehydration by salines, spinal drainage by repeated lumbar punctures, et cetera, has been successful in 71% of these patients, and it is only in 16% of the entire series of 217 cases that a cranial drainage by decompression was in-

dicated and performed. The advisability of the operative treatment of these acute conditions in adults is practically twice as common (29%) as it is in children and this is due, in my opinion, to the greater frequency and danger of acute traumatic cerebral adema in adults—not only to life but to future normality.<sup>1</sup> The operative treatment of cranial drainage was instituted only after the expectant palliative method failed in lowering the high intracranial pressure as estimated by the spinal mercurial manometer—whether this increased pressure has been due to cerebral hemorrhage or to cerebral edema alone. Never should the operative treatment be advised during the initial period of shock as the operation is but an added shock to the patient, nor during the terminal period of medullary edema, clinically pictured by rapidly rising temperature, pulse and respiration rates and a falling blood pressure, these patients all die and a cranial operation merely hastens the end.

2 *Intracranial Hemorrhage at Birth*—It is only within the past five years that cerebral birth hemorrhage of varying degree has been proven to occur much more frequently than was ever conceived, Schwartz<sup>2</sup> of Berlin has stated that "the pathology of the first month of life is completely dominated by the birth injuries of the brain", Fischer<sup>3</sup> of Basel has written that his postmortem observations at the Institute have convinced him that "the 10% of deaths during the first month are chiefly due to cerebral birth injuries", and Huenekens,<sup>4</sup> in a recent article says that "the recognition of cerebral hemorrhage of the new born is a most neglected phase in their care and yet it is a most important one." In my series of 500 consecutive newborn babies irrespective of the type of labor and upon whom a lumbar puncture was performed within 24-48 hours after birth by Doctors MacLaire and Espejo,<sup>(5)</sup> at the City Hospital, New York, 45 babies (9 %) had bloody or blood-tinged cerebrospinal fluid, repeated lumbar punctures of spinal drainage were sufficient to aid the normal absorption of the blood so that the cerebrospinal fluid became clear and under normal pressure,

## THE QUESTION!

What is the principle upon which success in substitute infant feeding depends? The Answer—See Nestle's Food Company, Inc advertisement on page ix of this issue of the JOURNAL—Adv

## SUMMER DIARRHEA

A formula well supported by clinical evidence is submitted for your consideration by the well known firm of Mellin's Food Company. Kindly note their advertisement on page xi of this issue of the JOURNAL—Adv

## PICKER SERVICE

Means a careful combing of the market of equipment and supplies

best suited to X-ray and Physiotherapy

Catalogue on request See the James Picker full page advertisement on page x of this JOURNAL—Adv

## TETANUS

It is becoming easier than ever before to give a child hypodermic of Tetanus Antitoxin, now that this biological product has been purified and concentrated to such an extent that 1,500 units (the prophylactic dose) resembles nothing so much as a few drops of pure water. Vast improvements have been made in the physical properties of Tetanus Antitoxin since the product was first made available to the profession, and with this improvement in form has

gone a constantly increasing use in caring for suspicious wounds

Doses as high as 20,000 units, for treatments, are now offered, in a volume no larger than that of the 10,000-unit dose of a few years ago, and from this point down to a 3,000-unit dose

See the advertisement in June 1—Page xxxi issue, headed "Tetanus Antitoxin (P D & Co)—Potent, Refined, Concentrated" It will well repay perusal—Adv

## NEW DE LUXE EQUIPMENT—BUY THE BEST

Our readers' attention is called to the advertisement of C M Sorensen Company on page xvi of this JOURNAL. They will be pleased to send you, upon request, folder fully describing their equipment. Every unit is sold under the firm's full guarantee—Adv

# Want X-Ray Supplies "P-D-Q"?

There are over 30 District Branches now established by the Victor X-Ray Corporation throughout U S and Canada. These branches maintain a complete stock of supplies, such as X-ray films, dark room supplies and chemicals, barium sulphate, cassettes, screens, Coolidge tubes, protective materials, etc., etc. Also Physical Therapy supplies.

The next time you are in urgent need of supplies place your order with one of these Victor offices, conveniently near to you. You will appreciate the prompt service, the Victor guaranteed quality and fair prices.

Also facilities for repairs by trained service men. Careful attention given to Coolidge tubes and Uviarc quartz burners received for repairs.

**VICTOR X-RAY CORPORATION**  
Main Office and Factory: 2012 Jackson Blvd., Chicago

closure of the cranial and spinal canal, in this manner resulted a partial blockage in the normal excretion of the cerebrospinal fluid through the walls of the supracortical veins, villi, et cetera, so that the subsequent increased intracranial pressure, in reality an external hydrocephalus, produced a protrusion of varying degree of the meninges at the site of weakest closure of the cranial or spinal canal—usually in the posterior midline of the head, the cervical area of the spine and, most frequently of all, in the lumbar vertebrae. Confirmatory evidence of the increased intracranial pressure in these cases is the frequent association of the spina bifida protrusion with external hydrocephalus of a degree sufficient to enlarge the head, in 47 per cent of my cases there was this clinical combination of spina bifida and hydrocephalus. Also the common observation that upon repairing the meningocele protrusion of spina bifida alone, very often the condition of external hydrocephalus develops within three to six months, this has occurred in 58 per cent of my cases of spina bifida operated upon, so that during the past five years I have always emphasized to parents this possible complication following the operative repair of the spina bifida and the necessity for early cranial drainage if the condition of hydrocephalus should develop later. It is very probable in these cases that the protruding sac of the spina bifida has permitted the absorption of sufficient amount of the partially blocked cerebrospinal fluid to avoid a marked increase of the intracranial pressure and then after the removal of this absorptive area in the operative repair of the spina bifida, there is no longer the escape for the blocked cerebrospinal fluid so that an increasing intracranial pressure develops, if not relieved, then the gradual enlargement of the head until clinically the diagnosis of hydrocephalus is only too evident. In several of these cases, I have had the opportunity of performing repeated lumbar punctures before the operative repair of the spina bifida and then at intervals following the operation and thus to be able to observe accurately the definite rise of pressure of the cerebrospinal fluid by means of the mercurial manometer until finally the increased pressure began to enlarge the head. Naturally, no longer are these patients permitted to wait until the head becomes enlarged before the diagnosis of hydrocephalus is made and the appropriate treatment instituted early. In this connection of increased intracranial pressure and its casual relationship to spina bifida and hydrocephalus, many observers have noted that as long as the leakage of cerebrospinal fluid from the spina bifida continues, rarely does the condition of hydrocephalus occur but whenever the spinal bifid sac closed and the area became dry, then the great danger of the complication of hydrocephalus. Chiefly for this reason, it has usually been advised in the past to delay any operative

repair of the spina bifida for a period of weeks and even months following birth in the hope that the complication of hydrocephalus might be avoided—even at the risk of permanent impairment of the legs due to connective tissue contraction at the site of the spina bifida. In my experience, the best results have been obtained in the cases of spina bifida repaired within the first three months after birth, being most careful to observe the intracranial pressure of the child at least once a month following the operation by means of ophthalmoscopic examinations and lumbar puncture tests until the child has apparently passed the danger of this complication, in one of my patients, however, hydrocephalus developed as late as thirteen months after the repair of the spina bifida.

**5 Brachial Birth Paralysis**—A flaccid paralysis of varying degree of one and rarely of both arms, observed within the first two days after birth and in the absence of temperature, can usually be definitely diagnosed as trauma to the brachial plexus. The lesion is most frequently a simple overstretching of one or more of the five nerve trunks of the brachial plexus due to the forceful torsion of the head in the difficulty of delivering the after-coming shoulder, therefore, the upper branches of the plexus are more commonly involved, resulting in the upper arm type of brachial palsy with the hand and fingers unimpaired. These milder cases of physiologic overstretching even to the degree of torn fibres within the nerve sheath usually improve rapidly so that within one to three months the arm is being freely moved. On the contrary, if the overstretching of any portion of the brachial plexus has been of a severity to produce a hiatus of its fibres and particularly of an entire nerve trunk, then a marked recovery of function is very doubtful—depending entirely upon unobstructed nerve regeneration. In those cases of complete separation of the nerve ends, it is indeed doubtful if many recover function spontaneously owing to the interposition of adjacent tissues and especially of organized unabsorbed hemorrhage. It is my belief that there are many cases of simple overstretching of the brachial plexus with no loss of continuity that would have made excellent recovery of function if the associated hemorrhage about the nerves of the plexus had been entirely absorbed, the formation of fibrous tissue of unabsorbed hemorrhage compressing the intact nerves is a common operative finding and thus prevents normal nerve conduction after the effects of the simple overstretching should have disappeared. The fact that the deep cervical fascia overlying the plexus is seldom torn in these cases naturally prevents the escape of this free blood into the tissues of the neck and thus lessens its absorption and increases the danger of resulting fibrous tissue compression of the plexus itself.

Fortunately, the vast majority of cases of brachial birth palsy make excellent recovery of

three of the babies in this series died and necropsy revealed extensive intracranial hemorrhage, supracortical and basilar

The clinical signs in the severe cases of extensive hemorrhage at birth may be unusual drowsiness to stupor, difficulty to refusal to nurse and muscular twitchings of the fingers and of either orbit and a clenching of the hands associated with a stiffness of the arms and legs even to the degree of generalized convulsive seizures. The clinical signs of milder degrees of cerebral birth hemorrhage may be most meagre and even apparently absent and unless a diagnostic lumbar puncture is performed, then the condition might pass unrecognized—and until recently in my experience, the lesion may not even be suspected. Fortunately in these milder cases, the natural means of absorption of the cerebrospinal fluid may "take care of" all of the free blood in the fluid so that no layer of clot remains upon the cerebral cortex or at the base and these are the cases that can and do develop normally, both mentally and physically. But if the amount of intracranial hemorrhage is larger than can be entirely absorbed by the natural means of absorption of the cerebrospinal fluid and yet the hemorrhage is not of sufficient amount to cause the death of the child, these are the cases for whom repeated lumbar punctures of spinal drainage may be of the greatest value in aiding its complete absorption, so that no organization-residue of unabsorbed hemorrhage remains to retard the normal development of the child. Unfortunately, the number of chronic cases of cerebral spastic paralysis upon whom a post-mortem examination confirms the diagnosis of cerebral birth hemorrhage indicates that this early treatment of the acute condition at birth when the fluid blood can be drained, is only too rarely used.<sup>6</sup>

In a large series of chronic cases of cerebral birth hemorrhage, they have usually been first born males at term, the labor difficult, with or without the use of instruments and especially following medium forceps and version with breech extraction, during the first week, drowsiness with difficulty in nursing and signs of cortical irritability, a gradual improvement after ten days until at one month the child is usually considered normal and so remains until the child does not hold up its head nor sit up within the normal period of time, the spasticity of legs or arms most frequently being observed during the seventh to the ninth month, the later retardation in walking and talking completes the clinical picture of the chronic condition when an improvement at most is only possible by any known method of treatment. As in acute brain injuries in children, the ideal time for treatment is during the acute stage at birth when the blood is in fluid form and can be drained and not months and years later. In my opinion, the lumbar puncture is the only accurate diagnostic method for the acute condition of intracranial

hemorrhage at birth and repeated lumbar punctures of spinal drainage are most valuable in its treatment

**3 Hydrocephalus**—In the diagnosis of hydrocephalus, it has been my experience that the complete blockage of the cerebrospinal fluid from the ventricles to produce the internal type of this condition is a relatively rare one and over three-fourths of the cases in children in my series diagnosed as hydrocephalus are of the external type—the ventricles not being blocked and therefore not dilated, thus in the external type of hydrocephalus, the normal channels of excretion of the cerebrospinal fluid through the walls of the supracortical veins, Pacchionian villi, etc., have become blocked by the organized new tissue formation of former meningitic exudate or of unabsorbed intracranial hemorrhage occurring most probably at the time of birth.<sup>7</sup> Even the internal type of hydrocephalus may be due to unabsorbed basilar hemorrhage and in several cases of my series upon whom diagnostic lumbar punctures revealed bloody cerebrospinal fluid at the time of birth, after a period of several weeks the condition of internal hydrocephalus has developed and in two of these cases at necropsy, the organization-residue of unabsorbed hemorrhage was found blocking the escape of cerebrospinal fluid at the foramina of Majendie and Luschka of the fourth ventricle. It is indeed fortunate that this condition of complete ventricular blockage is the uncommon type of hydrocephalus as its successful treatment is the most discouraging in neurosurgery—100 per cent failures in my series of cases, on the contrary, the successful drainage of the common external type of hydrocephalus is most encouraging—the end result depending entirely upon the etiological factor of meningitis or hemorrhage and upon its early diagnosis, to wait until the increased intracranial pressure produces tense, bulging fontanelles and finally an enlargement of the head before the diagnosis is suspected is to permit these cases due to unabsorbed hemorrhage to become permanently damaged by the prolonged increase of the intracranial pressure and thus the end result is at best merely an improvement. Early ophthalmoscopic examinations and the use of the mercurial manometer at lumbar puncture are most valuable aids in the early recognition of these conditions.

**4 Spina Bifida and Meningocele**—No longer is the condition of spina bifida and meningocele considered as being similar to hair-lip and cleft palate—i.e., a mere defect in the coverings of the central nervous system.<sup>8</sup> In 86 per cent of my cases, there has been demonstrated an increased intracranial pressure even in the presence of the meningocele protrusion and at operation or at necropsy the findings in varying degree over the cerebral and spinal cortices of organized new tissue formation of former meningitic exudate that had occurred most probably before the firm

tlement of a very complicated condition is not quite satisfactory, and he believes in this as in many other obstetrical conditions that we cannot generalize too much but must consider *each case as an entity*, the treatment elected to correspond to the conditions presenting themselves both as regards mother and child at the time, and that to say that *all* cases of placenta previa centralis, for example, should be subjected to an abdominal section, is just as fallacious as to say that *none* should. When the obstetrician can learn the lesson of individualizing his cases and not generalizing them, he will have gone a long way in the reduction of these mortality and morbidity figures.

With regard to the reader's cases, I should like with your permission, to quote rather extensively from an article read by me on the treatment of Placenta Previa at the annual meeting of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons at Philadelphia, in September, 1923, which represents my personal feelings today as well as it did at that time, and will serve to present the subject for your discussion.

"In the first place, for the purpose of studying results, it seems to me that the cases of placenta previa should be divided in two groups: the first, those in which there is a viable child, and the second, those in which the previa is discovered so early in the pregnancy that the possibility of a living child is not to be considered, or only secondarily.

"With this broad classification approved, the methods of treatment generally in vogue may be considered. The diagnosis being established by the ordinary signs and symptoms, familiar to all, the methods presenting are: packing the lower uterine segment, cervix and vagina with gauze, leaving it *in situ* sufficiently long to cause active labor pains and dilatation of the cervix, at the same time controlling the hemorrhage, introduction of a Vorhees bag designed to accomplish the same purpose, where sufficient dilatation already exists, rupturing the membranes, followed or not as the case may warrant, by the bringing down of the leg and allowing the labor to proceed, lastly the method of abdominal section.

"All of these procedures have their advocates and undoubtedly all of them have their place, but which method is to be applied to the individual case, is the problem which demands attention. A careful survey of the published figures of various authors, shows that there is a maternal mortality of from 5 to 20 per cent, with a foetal mortality ranging from 65 to 80 per cent.

"In December, 1907, I presented a series of two hundred and fifty cases from the wards of the New York Lying-In Hospital in which the maternal mortality was 18 per cent and the stillbirth mortality was 44.4 per cent. In the last

five hundred and ninety-one cases on the same service, seventy mothers died, a mortality of 12.1 per cent, with a stillbirth mortality of about 42 per cent. A considerable improvement in the maternal mortality, but only a very slight one in that of children. Again many of the children died within the first few days, due to prematurity, for in the five hundred and ninety-one cases three hundred and seven or more than half the total, were premature.

"In my recent series already mentioned, the preference in treatment was given to gauze packing, followed in most instances by an internal podalic version, this being done in 354 out of 591 cases. There were 34 abdominal Caesarean sections, two extraperitoneal Caesarean sections, three vaginal hysterectomies, 20 Braxton-Hicks operations, 43 breech extractions and 22 craniotomies on dead children, the rest being made up of forceps and normal deliveries. The resultant mortality to the mother, as already stated was 12.1 per cent with a stillbirth mortality of 42 per cent. One hundred and seven children, born alive, died before leaving the hospital, or about 18 per cent, a total foetal mortality of slightly over 60 per cent.

"Granting that in many instances, perhaps in the greater proportion, the mothers were greatly exsanguinated on entrance to the hospital, that the children were premature or not alive when first seen, all of which conditions must necessarily prevail in an acute service, it will be well to observe from experience what seems to be the most satisfactory way of handling these cases.

"No one thing has contributed more to the successful issue in placenta previa, as far as the mother is concerned, than the practice of blood transfusion, so that in all cases as soon as the diagnosis is established, the mother should be grouped as to her blood and a satisfactory donor obtained whose presence should be maintained within easy reaching distance until the necessity for his or her services is no longer needed for the patient. The factor of time in giving a transfusion is of the utmost importance, as well as that of proper technic, and it follows then, as a matter of course, that the patient should be in a well equipped hospital which in these days is practically always available.

"Having made the diagnosis, *immediate treatment* should be instituted without procrastination, and one of the recognized methods of operation employed. From my experience and the reports of others, it would seem that if the patient has an undilated or slightly dilated cervix, is at term or nearly so and has a living child, that an abdominal Caesarean section rapidly performed by a competent operator offers the best solution for mother and child, this applying to primipara multipara alike. If the patient is in fair condition when first seen, and has not been infected by injudicious manipulation, the ensuing result

function within three months after birth, with and without any special treatment other than the routine massage and exercises (being most careful to avoid any tension and depression upon the shoulder), the use of the aeroplane splint of abduction and external rotation of the upper arm, et cetera. Those patients, however, that do not improve markedly during the first three months and especially the ones still impaired at six months after birth, should have the benefit of a small skin incision over the plexus in order that the nerves may be inspected and any lesion repaired early—and not months and even years later when muscular contractures and deformities have occurred and when the best result possible is an improved arm. Even with early operation and a successful anastomosis of the nerves, never can a normal arm in all respects be obtained, but the earlier the lesion is repaired, just so much better is the end result.<sup>9</sup>

In conclusion, permit me to emphasize again the importance of early diagnostic lumbar puncture and the great therapeutic value of repeated lumbar punctures of spinal drainage in many of

the neurosurgical conditions affecting the newborn and children. Using the mercurial manometer to estimate accurately the pressure of the cerebrospinal fluid and never withdrawing an amount of fluid sufficient to lower this pressure more than one-half, no longer is this method of diagnosis and drainage a procedure of last resort. To permit patients, adults as well as the newborn and children, to die or to become permanently impaired by a prolonged increase of the intracranial pressure upon the brain without ascertaining early and accurately the intracranial status by this method, cannot be too strongly condemned.

### THE TREATMENT OF PLACENTA PREVIA\*

By ROSS McPHERSON, M D, F A C S, NEW YORK, N Y

THE treatment of the type of obstetrical complication known as placenta previa, or in other words, the pregnancy case where the placenta has its uterine attachment low down on the uterine wall, either partially or nearly entirely covering the os uteri, is one which apparently never ceases to be an active subject for discussion and argument on the part of the obstetrician. In general, the maternal and foetal mortality is so high, complications so numerous, and the opinions of various experts as to the proper method of procedure are so varied that at times it seems as if we had reached a point in this particular abnormality where we were at a dead centre and improvement hard to obtain.

If we follow the method employed in the Tuebingen Clinic, reported in the *Archiv fur Gynaekologie* (1923, cxviii, 120) by Gaenssle, we have a perspective founded on the analysis of 186 cases. Ninety-three of these were treated by vaginal route with a maternal and foetal mortality of 8.6 per cent and 54 per cent respectively. Ninety-three were treated by abdominal Caesarean section with a maternal and foetal mortality of 6.4 per cent and 6.4 per cent respectively, surely a striking difference in the foetal and an improvement in the maternal mortality.

Bonwer in the *Nederlandsch Monatschrift voor Geneesbunde* (1924, xii, 269) reports 6

per cent maternal and 17.5 per cent foetal mortality for placenta previas where Caesarean section was performed, as opposed to a considerably higher maternal and a much higher foetal mortality running where the Braxton Hicks method was employed as high as 77.8 per cent.

Schoenholz reporting from the Dusseldorf Clinic (*Monatsschrift fur Geburtshilfe und Gynaekologie*, 1924, cxv, 112) quotes a maternal mortality of 2.08 per cent and a foetal mortality of 6.5 per cent where Caesarean section was employed. These reports are but a few of several all tending to show that the employment of Caesarean section offers the best chance for the life of the child and mother in the occurrence of placenta previa.

Kellogg of Boston (*American Journal of Obstetrics and Gynecology*, Vol XI, No 2, pp 194-) states that while in 1915-1920, the maternal mortality at the Boston Lying-In Hospital had dropped to 6 per cent where conservative methods were used, that in the next five year period, with the same treatment it had risen to 10.5 per cent and that the foetal mortality had risen also. He concludes that the more frequent employment of Caesarean section in central and partial placenta previas is warranted.

It will thus be seen that there is a distinct tendency on the part of many operators to consider abdominal section in this condition. To the reader, however, this somewhat arbitrary set-

\* Read at the Annual Meeting of the Medical Society of the State of New York, at New York, March 31 1926

siderable part of the time. The patient complained of headache a great deal. There were chilly periods during the day, and profuse sweats each night.

Typhoid fever was considered in the diagnosis. A specimen of feces examined March 14, was negative for organisms of the typhoid-paratyphoid group. On March 19, serum was obtained for agglutination against typhoid organisms. A blood culture in dextrose broth was made, and a blood smear prepared. No counts of leucocytes or erythrocytes were made. The blood culture was incubated for two days, and examined daily. Results of the examination were negative, and the culture was then, unfortunately, discarded. Tests with the serum against typhoid and paratyphoid organisms were completely negative. Examination of the blood smear showed normally staining red blood cells. A differential count of the leucocytes gave the following: neutrophiles, 59 per cent, eosinophiles, 1 per cent, basophiles, 2 per cent, lymphocytes, 21 per cent, large monos, 17 per cent.

In view of the paucity of physical findings, and the negative agglutination tests in the third week of the disease, the likelihood of typhoid and paratyphoid fever was then discounted, and thought given to the more unusual causes of continued fever. Tularemia and Undulant fever were considered. The clinical course of the illness being more suggestive of Undulant fever, the balance of the serum remaining after the agglutination tests was submitted to the Division of Laboratories of the State Department of Health, with the request for tests against *Brucella Abortus* and *Brucella Melitensis*. The Laboratory reported positive results with their stock strain of *B. Melitensis* in dilutions as high as 1:320.

Due to difficulties of transportation to the patient, he was not again seen for purposes of laboratory study, until April 4. By this time he had somewhat recovered, and had been without fever for two days. It was interesting to note that, while the patient had the appearance of one who had been sick, he showed much less emaciation than would be expected after his long continued pyrexia. A blood culture was obtained from him at this time, and a specimen of blood for further

agglutination studies. Inquiry brought out the fact that there had been an abortion among the cows on his farm late the preceding Fall, and several cases of abortion in the farm adjoining. Examination of the blood culture was negative. This was to be expected, however, since it was obtained late in the disease, and when the patient was afebrile. The blood for the agglutination studies was submitted to the laboratory of the State Veterinary College at Ithaca. This laboratory reported positive results with both *B. Abortus* and *B. Melitensis*, with agglutination in a titre 1:400 with the former, and 1:135 with the latter. Absorption of agglutinin tests were conducted, and demonstrated that the infection was due to *B. Abortus*.

On April 24 and 25, the patient again had fever, the afternoon temperature reaching 100. He was seen on April 26. A specimen of urine was obtained, in the hope that the organisms might yet be recovered. Guinea pigs were inoculated from this specimen, and are at present under observation.

The patient is at present nearly recovered, and able to be up and about. He has had no attacks of pyrexia since April 25.

Largely through the cooperation of the State Veterinary College studies have been made on the herd on the farm on which the patient lives. Of the 13 animals, 12 showed definite serological evidence of infection with *B. Abortus*. The strongest reaction was obtained in the cow whose milk was used solely by the patient and his family.

#### SUMMARY

In the serum of a patient with undulant pyrexia definite agglutination was obtained with *B. Abortus* and *B. Melitensis*, and agglutinin absorption tests have demonstrated *B. Abortus* infection. The disease has apparently run a self-limited course under expectant treatment. The history of the case bears out the idea that there is a connection between contagious abortion in cattle, and Undulant fever in man. Undulant fever, caused by *B. Abortus*, must be borne in mind by the physician in the diagnosis of obscure fevers of a duration of more than a few days.

should vary little from that of similar operation done for some other indication. If, on the other hand, the child be dead or nonviable, one of the other less drastic means of delivery may be employed, and of these in general I am inclined to favor tamponade with iodoform gauze strips. This will, in practically all instances, control the hemorrhage, especially if the membranes are first ruptured, it stimulates labor pains, causing dilatation of the cervix, stays where it is put until removed by the operator, which is not always the case with hydrostatic bags, and if applied under aseptic conditions, is, in my opinion, not as potent a source of infection as commonly believed. Iodoform is used in preference to plain gauze because it resists putrefaction longer than plain gauze, and if packed tightly rarely gives rise to iodine poisoning. The gauze should be firmly packed as far up as it will go into the uterine cavity, the cervix filled, as well as the vaginal fornices, and the vagina. Such a pack in nearly every instance thoroughly controls hemorrhage and may be left *in situ* for a considerable time without cause for worry.

"When the patient has had hard contractions for some time and it is judged that the cervix is sufficiently dilated to allow the extraction of the child, she may be placed on the operating table, an anesthetic administered, under the best

aseptic precautions, the packing removed and the extraction proceeded with in the manner chosen by the operator. I usually remove the placenta manually and repack the uterus. Care should be taken not to handle the cervix more roughly than necessary, as in these cases it is very friable and more apt to tear, thus promoting hemorrhage and subsequent infection. A transfusion should be ready at the time of delivery and if there is any doubt at all of its necessity, it should be given without delay. Pituitrin and ergot may be used after delivery and uterine packing to aid in contracting the uterus.

"I believe that most of the maternal mortality in placenta previa is due to delay in diagnosis of the condition, accompanied by tardiness in treatment, combined with careless manipulation and resultant infection, all of which are preventable and inexcusable. If these factors are eliminated, as they can be, the results for the mother should be much improved and a patient will rarely be lost. Regarding the foetal mortality, so much cannot be said, as the greater majority of the children are so premature that little can be done to save them even if born alive. Caesarean section on the viable fetus, does offer a means of lowering this mortality to an appreciable degree and should be employed in this class of cases more frequently."

## UNDULANT FEVER IN CATTARAUGUS COUNTY—REPORT OF A CASE\*

By MYRON E FISHER, M.D., DELEVAN, N. Y.  
JOSEPH P. GAREN, M.D., OLEAN, N. Y.

**R**ECENTLY a number of cases of Undulant Fever have been reported, and evidence is accumulating to the effect that the disease is more frequent and widespread than commonly supposed. Although the clinical picture and laboratory findings differ from those of typhoid fever, it is reasonable to assume that many cases, diagnosed and treated as typhoid fever, are actually cases of infection with *Brucella Abortus* or *Brucella Melitensis*.

Carpenter and Merriam<sup>1</sup> report two cases of Undulant Fever, due to *Brucella Abortus*, occurring in Ithaca in 1925. Recently Carpenter<sup>2</sup> has seen a third case in Ithaca. In addition many infections have been reported by other observers.

The widespread distribution of infection with *Brucella Abortus* in cattle and other farm animals together with the acceptance of the knowledge that *Brucella Abortus* is under certain conditions pathogenic for man, renders it necessary to consider the possibility of infection with *Brucella Abortus* in the differential diagnosis of fevers of long duration.

### REPORT OF A CASE

E. F., a farmer, aged 23, past history irrelevant, had enjoyed general good health until the beginning of the present illness. He had never been outside New York State, and for the past year had been to but few nearby places. About February 27, he began to feel sick. He tired easily, and felt feverish and chilly by turns. By March 6, he felt too ill to remain up, and called a physician. His temperature on this date was 103. From this time on accurate temperature records were kept. The afternoon temperature each day was between 103 and 104, and the morning temperature 99. Careful physical examination by the attending physician was quite negative. Examinations of the head and neck showed no abnormality. The lungs and heart were normal. There was no enlargement of the lymph glands, and the spleen was not palpable. No eruption was noted on any part of the body. The pulse was strong, with a rate ranging from 80 to 90, and markedly dicrotic (this characteristic persisted over a period of three weeks). There was diarrhoea for a con-

## THE TREATMENT OF PNEUMONIA WITH OXYGEN

By JOSEPH R. WISEMAN, A.B., M.D., SYRACUSE, N. Y.

Professor of Clinical Medicine, College of Medicine, Syracuse University

UNTIL recent years, the use of oxygen in the treatment of pneumonia had been most unsatisfactory. Usually the patient was allowed to struggle for some days against a severe infection until marked cyanosis had developed. The oxygen tank was then rushed to the bedside, and a funnel was held over the patient's face for varying intervals of time. The termination was almost uniformly fatal, and the appearance of the oxygen tank at the bedside came to be regarded as a sign of impending dissolution. The difficulty lay, not in the soundness of the procedure, but in the method and the time of its application.

Most pneumonia patients battle against two foes, infection and anoxemia. Apart from the comparatively few cases that are amenable to specific sera, we have no means of directly overcoming the infection with its toxemia. The anoxemia, however, can be successfully relieved by properly applied oxygen therapy.

The arterial blood of a normal resting individual is nearly 100 per cent saturated with oxygen. With diminution in the percentage of oxygen saturation, the individual begins to show signs of oxygen want, and when the deficiency reaches 20 per cent, he suffers severely. The amount of cyanosis shown by an anoxemic patient quite closely parallels the degree of oxygen deficiency.

The harmful effects of anoxemia alone, without the addition of pneumococcus infection, are sufficiently serious to cause grave concern. The internal cell respiration and nutrition are interfered with, cell function becomes altered, and in oxygen sensitive tissues like the nervous system, cell degeneration can actually occur. The pneumonia patient therefore often fights his disease under a heavy handicap. The infection alone he might be able to subdue if given a fair chance, but infection plus anoxemia often prove too great a burden. The patient is like a mountain climber who is forced to attempt a lofty peak carrying a heavy pack, instead of going lightly clad.

One of the first things accomplished by the work of recent years has been the demonstration of the utter inadequacy of the funnel method. The oxygen diffuses into the surrounding air, and only negligible amounts are inhaled by the patient, with no therapeutic results. Barach<sup>1</sup> believes that the 21 per cent of oxygen in the inspired air must be raised to 30 per cent in order to be slightly effective. He considers 40 per cent the optimum concentration, although amounts up to 60 per cent are well tolerated. Higher concentration

should not be administered for long periods.

At present we have at our disposal a number of methods of oxygen administration which give different degrees of effectiveness, and can be varied to suit the individual patient.

The nasal catheter method is ranked by Barach as slightly effective. A small rubber catheter, with four holes placed within the terminal inch, is passed along the inferior surface of the nasal cavity until it strikes the nasopharynx. It is then withdrawn one half inch, passed over the forehead, and fastened with adhesive plaster. If oxygen is bubbled vigorously, and the patient does not institute mouth breathing, a 30 per cent concentration may be reached. It is best to use high pressure tanks of commercial oxygen containing 110 or 220 cubic feet, such as are used by garages for oxyacetylene welding, rather than small tanks of low pressure medical oxygen. Commercial oxygen is equally suitable and much less expensive, an important point when administration is continued for long periods. The high pressure tank must be equipped with a suitable reducing or metering valve.

During the World War oxygen was frequently administered by means of a face mask, and various modifications of the method have been proposed. It is suitable for comatose, or apathetic patients, but those who are conscious often object to its use.

A rebreathing apparatus may be used, with soda lime to absorb the carbon dioxide. Barach recommends that a glass tube be fitted into one nostril and connected by appropriate tubing with the apparatus. The patient then breathes room air through one nostril and oxygen through the other. If nasal breathing is not satisfactory, a mouth-piece may be substituted.

Various types of oxygen tents have been devised in which patients breathe an oxygen rich atmosphere. Guedel<sup>2</sup> speaks highly of a simple tent made by cutting in two a barrel hoop of 24 to 30 inches diameter. The two halves are crossed and tied together in the center to make a frame which is roughly hemispherical. Over the frame, an ordinary muslin sheet is thrown and tucked in at the sides. A rubber tube leading from the oxygen tank, which is equipped with a metering valve, is led in through a small opening in the sheet. The latter should not be too thick or the patient will complain of heat. The method does not provide a window through which the patient may be watched, but is valuable for its simplicity and for its applicability either to home or hospital treatment.

# OBSERVATIONS OF PATHOLOGICAL CONDITIONS AND DISTURBED FUNCTIONS OF THE SPECIAL SENSE ORGANS AND THEIR RELATION TO THE PSYCHOSES

By GEORGE E. DAVIS, M.D., NEW YORK, N. Y.

A LARGE experience at the Central Islip State Hospital for the Insane during the past eighteen years has been both interesting and instructive.

Pathological conditions and disturbed functions of the special sense organs affect the individual's psychic more profoundly, perhaps, than lesions and impaired functions of other parts of the organism. And this is a reasonable deduction when we consider the bearing that involvement of these special organs exert on the welfare and happiness of the individual. Stressing the above premises, however, should not render us unmindful that other somatic pathologic processes, even remote from these special organs, may exert a marked deleterious effect on the *mental equilibrium*. Particularly is this so as regards focal infections in whatever region located. "I am convinced that the somatic toxæmias frequently are potent contributing factors in developing many borderline cases of mental unbalance into full fledged psychoses. Like the last straw that breaks the camel's back they push the patient "over the top" into "no man's land"—or the realm of unreason. That accumulations of toxins from focal infections produce adverse effects on the physical condition is unquestioned and that they may precipitate a psychosis is plausible. Moreover, unless the infective foci are removed these attacks may be prolonged or repeated time and again.

In dealing with the physical we are all familiar with chronic toxic cases which periodically suffer sudden exacerbations or explosions as in migraine, angina pectoris, neuritis, gout, etc., due in all probability to excess toxic accumulations. Reasoning from analogy, we may infer that the mind will be frequently and profoundly affected under similar conditions. But, *vice versa*, the psychic likewise affects physical phenomena and functions—as psychic blindness and deafness.

Pavloff and other investigators have shown that malfunctioning of other vital organs, aside from the special sense organs, may result from the stress of such wearing or overwhelming emotions as worry, fear, grief, envy, anger, etc. Perverted endocrine functions not infrequently ensue from emotional disturbances also.

In examining the insane, we are prone to rely on psychoanalysis to the exclusion of physical investigation, disposed to attribute all psychoses to some gradual, prolonged mental stress, else to some overwhelming emotional disturbance, rather than to somatic lesions or perverted body functions. Probably the somatic toxæmias and perverted endocrine functions play a greater role in the etiology of the psychoses than we imagine.

I have had no experience in endocrine therapy in the psychoses, but very extensive experience in removing foci of infection located in the ears, sinuses, tonsils, pharynx, etc., and am fully convinced that the elimination, surgically or otherwise, of somatic toxæmias facilitates the alleviation and, in some instances, the complete and permanent relief of these cases.

Here I wish to note a point worthy of record, i. e., with kind handling and some tact, the insane are unusually amenable and easily controlled during serious operations under *local anæsthesia*. Probably because they are not given to worry over results, convalescence is generally more prompt.

For the above reasons much of my surgical work is done under local anæsthesia with these patients, in fact, with the exception of mastoidectomies, practically all tonsil, sinus, septum, and plastic operations, even of a radical nature. In the hundreds of operations done under local anæsthesia it has been necessary only in one instance to resort to general anæsthesia to complete the work. Moreover, many of these cases are systematically septic from severe focal infections and it is well understood that very toxic patients do not tolerate general anæsthesia well. General anæsthesia is terrifying to nearly all the insane, therefore all the more reason for local anæsthesia in all cases where it can possibly be employed.

In conclusion I would state that it cannot be stressed too strongly that the diagnosis and treatment of the psychoses embrace a mutual consideration of the intimate interrelation and interaction of mind and body and we should conduct our investigations and therapy accordingly.

lips is unchanged. She is now up for part of the day.

Too great optimism over the use of oxygen as one of the newer forms of treatment would be entirely unwarranted. Oxygen therapy can only accomplish one thing—the restoration to normal of the oxygen saturation of the blood. It is not intended to supplant the use of sera or any of the accepted forms of treatment, but is an addition to them. It cannot overcome in-

fection or toxemia, but by relieving the patient of a serious embarrassment, it gives him a better chance to fight. Although the number of cases reported in the literature is still small, many of them have been very carefully studied under most favorable surroundings. A definite number of patients who appeared to be hopelessly ill have recovered. The method is based upon sound physiological reasoning, and is worthy of wider use.

## ON PROVING THE DIAGNOSIS OF SUSPECTED DIABETES MELLITUS

By J ARTHUR BUCHANAN, M D, M S, BROOKLYN, N Y

THE diagnosis of a well marked case of diabetes mellitus requires little effort. The repeated daily finding of sugar in the urine in association with a blood sugar quantity that is above the normal establishes the diagnosis. A blood sugar of 160 mg in each 100 cc of blood two hours after eating a full meal is considered the maximum normal. The vast majority of determinations show not over 115 mg in that quantity of blood. During the last two years a number of patients in whose urine sugar had been found on various occasions have consulted me in the hope of determining the existence or non-existence of a true diabetes mellitus. The usual recommendations for the study of this problem are so cumbersome and often so uncertain as to results that many patients go a considerable length of time before the question is settled.

The glucose tolerance test by oral administration has not been conclusive in the hands of many physicians, because of variations in the absorption rate in the intestines. The subcutaneous and intravenous methods of carrying out the test are impracticable in the ordinary care of patients. Furthermore, the test requires more time than the average practitioner can give to the individual patient.

If a patient has diabetes mellitus, there is a degree of deficiency in the normal output of the secretion of the insular tissue of the pancreas. This secretion, known as insulin, is necessary for the metabolism of carbohydrates. The quantity of the secretion produced under normal conditions is not known. It is evidently very large, and, perhaps, regulated by the demand, as carbohydrates are metabolized when sudden demands arise without sugar appearing in the blood in excess, or in the urine. The fact has long been established that a person with diabetes mellitus or insulin deficiency cannot eat the same quantities and quantities of food as a normal person without developing a blood sugar that is higher than normal, with or without sugar appearing in the urine.

The digestive and intestinal absorptive faculties of a patient remain the same for the same type

of food under ordinary circumstances. A test conducted while the patient follows the daily routine of eating offers a method of studying suspected cases of insulin deficiency that takes into consideration the constant or varying functional capacity of the intestines as well as the secretory power of insular tissue. The time factor as in the glucose tolerance test is not important. The daily routine calls made on the insular tissue are tested, and if the response is sugar in the urine and a blood sugar above normal, the existence of a deficiency is established, even if the deficiency be very slight. The test is comparable to the best one for myocardial efficiency, namely, the ability of the heart muscle to take care of the daily demands placed on it without the production of symptoms.

### ROUTINE OF INVESTIGATION

On the first day of the study, the blood sugar is determined, and the urine examined for sugar. The hour in relation to the previous meal is noted, as there is little valuable information obtained by determining the blood sugar until two hours after the previous meal. The subsequent studies are repeated at the same hour. The patient is instructed to eat full meals for twenty-four hours, and to save all the urine passed during the period. The blood sugar is determined, and the urine examined for sugar at the end of the twenty-four hour period. If insulin deficiency is present to any marked extent, the blood sugar will be considerably elevated, and if the degree is marked in the presence of a normal renal threshold, sugar will be found in the urine. If there is sugar in the urine or not, and the blood sugar is normal, the same program is carried out for one week. If the blood sugar is 125 mg or to 160 mg in each 100 cc of blood, the same program is followed for a second period of 24 hours. During the second period candy is eaten between meals. If at the end of the second twenty-four hour period the same situation exists the patient is instructed to live on a full diet for one week. In no patient with a blood sugar of

Barach has devised a portable oxygen tent which presents many desirable features. The head and shoulders of the patient are enclosed by a tent of impervious material with windows through which the patient can be observed. Oxygen is circulated by a blower, with an ice chamber for cooling purposes, and soda lime to remove carbon dioxide. With the surrounding air at 96 F, the temperature inside can be kept at 72 F, and the oxygen concentration suitably adjusted. A high degree of comfort and efficiency can be obtained.

Finally, we have the oxygen chamber containing the patient in bed, where by the use of rather elaborate apparatus the air can be kept at any desired concentration of oxygen, and the temperature, moisture and carbon dioxide accurately controlled. Medical and nursing care are not interfered with. The chamber is ideal for patient and physician.

When should treatment be started? Just as soon as the first signs of anoxemia appear. Samples of arterial blood may be taken for accurate estimation of oxygen saturation, but practically the presence and degree of cyanosis are usually good guides. Occasionally an ashen gray color indicates anoxemia. Guedel advises that sufficient oxygen be given to keep the finger nails pink. Treatment should be continuous, subject to necessary interruptions for medical and nursing care and may have to be kept up for several days. Where continuous treatment is impossible, the intermittent inhalation of oxygen is of some benefit. Favorable results are clearing of the cyanosis, slowing of pulse and respiration, improvement in the mental and nervous condition, and sometimes relief of dyspnea.

The following case of bronchopneumonia is cited merely as an illustration of method.

Mrs. G., aged 65, the mother of eight living children, has been somewhat short of breath since marriage. She has had frequent attacks of acute bronchitis and successfully overcame a severe pneumonia four years ago. The lips have been cyanotic for more than ten years, and disseminated fine moist rales have been present in both lungs for several years. In spite of this disability she has worked hard up to recent years and has enjoyed a fair degree of health.

Nov. 18, 1926, she was taken with a cough and general malaise, but kept up and about for a day or two. Fever developed with increased cough, shortness of breath and prostration. When I saw her on Nov. 23rd she was moderately dyspneic with definite cyanosis. The lungs showed no areas of dulness but presented numerous fine and medium moist rales from apices to bases. The rales were partly expiratory but mostly inspiratory, and in certain areas had a consonating quality. Over the

cardiac area which was slightly enlarged to the left, a blowing systolic murmur could be heard. The second sound of the heart was not audible. The following day the patient appeared worse. Cyanosis of the lips, ears and fingers was very marked. The face had an ashen purplish color. Hospital treatment was advised and was reluctantly accepted by the patient. Upon entering the Syracuse Memorial Hospital the same day, oxygen treatment was at once started. A good sized cradle, such as is used to support the bed clothes in fracture cases, was adjusted about the patient's head and shoulders and a sheet thrown over it to make a tent. A rubber tube was led in from a high pressure oxygen tank and oxygen was allowed to bubble vigorously at the rate of five liters per minute. The patient soon became quiet and breathed more easily, the pulse was slower and stronger, and she showed definite improvement in color. Whenever the tent had to be thrown back to allow nourishment or medicine to be given, the cyanosis would return, but would again improve as soon as oxygen was started. At no time, however, were we able to overcome the cyanosis completely. The temperature averaged from 100° to 102°. The leucocyte count was 9,000 with 80 per cent polynuclears. The sputum showed a mixed infection with a few pneumococci of type IV.

The patient was at no time satisfied to be in the hospital and kept asking to be taken home. Oxygen treatment was continued night and day for 48 hours up to her departure from the hospital. Her condition had grown steadily worse and the afternoon of her last day in the hospital, Dr. I. H. Levy, who saw her with me, felt that a fatal issue was to be expected. She again asked to be taken home and the family, feeling that it might be her last wish, decided to gratify it. The oxygen apparatus was transferred to the patient's home but she refused to have it used although she was intensely cyanotic after the ride home in the ambulance. Dr. J. J. Buettner was sent for and he succeeded in inducing her to inhale pure oxygen through an anesthetist's face mask. This was given for a few minutes at a time over a period of about an hour. Cyanosis would be replaced by a pink skin during oxygen inhalation but would return when it was stopped. During the night the nurse occasionally succeeded in giving concentrated oxygen at brief intervals.

The next morning, to our surprise, the patient seemed better and a recovery began which has been protracted but uninterrupted. The myocardium appeared to be severely damaged and general strength was slow in returning. Scattered fine and medium moist rales are still present. The chronic cyanosis of the

month after the operation sugar was found in the urine, and the patient was told that he had diabetes mellitus. He began dieting, and rapid loss of weight followed. Sugar was not found again in the urine. Four months after the operation, he consulted me to find out if he had diabetes mellitus. The results of the study are shown in Table IV.

TABLE IV

	Urine Sugar	Blood Sugar
First day . . .	10%	120
At end of 24 hours .	00	118
At end of 48 hours .		
At end of 1 week ..	00	110
At end of 1 month . .	00	110

This patient was told that he did not have diabetes mellitus, and to discontinue dieting. Subsequent observations have proven the correctness of this advice.

Case 5 J. W. L., male, aged 61 years. On May 22, 1923, 0.8% of sugar was found in the urine. The finding was made in the course of a search for the cause of declining health produced by multiple pains of a marked character. He consulted several physicians, and sometimes sugar would be found, the reverse on other occasions. On Dec 8, 1924, 1.3% of sugar was found in the urine. He had this report from a chemical laboratory. He was then treated for sugar in the urine for some time, but after a course of treatments by injections in the arm, the sugar cleared up, and he was told that he had

no more trouble. For the ensuing two years he consulted no more physicians. Because of a continuous decline in weight, he consulted me in the early part of Jan., 1926, and wished to know if he had diabetes mellitus. He had no symptoms of the disease, and the results of my investigation are shown in Table V.

TABLE V

	Urine Sugar	Blood Sugar
First day . . .	0	1600
At end of 24 hours ..	5%	333.3
At end of 48 hours . . .	10%	430.0
At end of 1 week . . . .	0	105.3
At end of 1 month .	0	105.3

At the end of 48 hours, the patient was put on a desugarization diet, and subsequent observations have confirmed the diagnosis of diabetes mellitus.

#### COMMENT

The method used has given conclusive and accurate data. It is easy of application, and will save patients a great deal of anxiety. The study necessitates a blood sugar determination, as occasionally patients are encountered who have no sugar in the urine, or very little, but have a blood sugar that is very high. There is nothing to be gained by considering these patients potential diabetics, as they are not satisfied until they are told that they do not at that particular time have the disease. It is impossible to see the eventualities in the life of any patient.

160 mg in each 100 cc of blood at the end of 24 hours on a full diet has a failure to prove true the diagnosis of diabetes mellitus occurred. At the end of one week the same tests are carried out. If positive information, constant high blood sugar two or more hours after eating a full meal with or without sugar in the urine, of diabetes mellitus is then not obtained, the patient is instructed to live on a full diet for one month, when the blood and urine are again examined. If the examination is then negative for positive evidence of diabetes mellitus, patients are told positively that they do not have diabetes mellitus. Patients are not satisfied by being told that they are potentially diabetic. The chance of this type of patient developing diabetes mellitus after such an investigation is so small that nothing is to be gained by keeping the patients in a prolonged state of anxiety. The physician runs practically no chance of giving information that can be proven inaccurate.

#### ILLUSTRATIVE CASES

Case 1 J L, male, aged 48 years. In November, 1924, sugar was found for the first time in the urine. During the next several months sugar was found a few times in the urine, but in very small amounts. He was placed on a diabetic diet, and told to consider himself a potential diabetic. He was first examined by myself on May 12, 1925. The results of the study are incorporated in Table I.

TABLE I

	Urine Sugar	Blood Sugar
First day	Ft trace	95
At end of 24 hours	0	110
At end of 48 hours		
At end of 1 week	0	110
At end of 1 month	0	105

The patient was told that he did not have diabetes mellitus, nor was there anything to be gained by treating himself as a potential subject for that disease. Subsequent observations have substantiated the advice.

Case 2 R F, Male, aged 42 years. In the early part of May, 1924, sugar was found in the urine during the course of an examination for stomach trouble. The blood sugar was reported to be 180 mg in each 100 cc of blood. A few times later the urine was found to contain sugar, but the blood sugar was always normal. Shortly after the examination, the patient began to lose weight, and dropped from 220 lbs to 162 lbs. He was dieting, and worrying a great deal, because his mother had died from diabetes mellitus. Shortly after the original diagnosis was made, he changed physicians, and this physician found no sugar in the urine. He was kept on the diet. For the next two years, he changed physicians

frequently, in an endeavor to prove if he had diabetes mellitus. On a few occasions sugar had been found in the urine, but the blood sugar was entirely normal. The results of my investigation are shown in Table II.

TABLE II

	Urine Sugar	Blood Sugar
First day	0	110
At end of 24 hours	0	110
At end of 48 hours		
At end of 1 week	0	111
At end of 1 month	0	100

This patient was told that he did not have diabetes mellitus, and to discard his diets. There has been a rapid gain of weight, and vigor. There was no evidence to warrant suspecting that he was a potential diabetic.

Case 3 S H S, Female, aged 48 years. In May, 1922, she began to be bothered with loss of strength, dreadful thirst, polyuria, and back-ache. Sugar was found in the urine, and following a short period of dieting, the sugar disappeared. No more sugar was found until October, 1925, when she developed intense itching of the vulvae. She again dieted, and no more sugar was found. She then became doubtful that she had diabetes mellitus, and consulted a good many physicians who told her that she did not have the disease. Just before I saw her she had had a glucose tolerance test, which gave a debatable result, and she was assured that she did not have diabetes. The results of my study are shown in Table III.

TABLE III

	Urine Sugar	Blood Sugar
First day	0.64%	166.7
At end of 24 hours	3.0	230.0
At end of 48 hours	4.0	330.0
At end of 1 week		
At end of 1 month	0	110.0

At the end of 48 hours, the patient was told that she had diabetes mellitus, and desugarization diet was instituted. Subsequent observations have confirmed the diagnosis.

Case 4 J H, male, aged 36 years. In 1925, following an attack of abdominal pain, 4% of sugar was found in the urine. The blood sugar was 125 mg in each 100 cc of blood. The next day the urine contained 2% of sugar, and the blood sugar was 118 mg in each 100 cc of blood. Two months later, the urine contained 2% of sugar, the blood sugar was 125 mg. After fasting for 12 hours, the urine was sugar free, and the blood sugar was 110 mg. The patient had an operation at this time for chronic cholecystitis, and subacute appendicitis, both of which were found at the time of operation. One

there was a definite impairment of both remote and recent memory. He thought he was in a hotel in Vienna or Cologne, he thought he was back in the Imperial German Artillery in which he had served before he came to the United States. He saw himself taking part in a battle, or drinking and having a good time with his friends in New Jersey. He was now fishing and swimming at his country place and then in a dark cellar, or in a hotel lobby, or in a taxi dashing through rain covered streets, or on a liner in mid-ocean. At no time did the thought that he was ill occur to him, although he did remember the nurses and the X-ray rooms, and fleetingly recognized them as such.

His haemoglobin was 68%, R B C 3,600,000, W B C 12,000 with 83% polymorphonuclear leukocytes. Blood Wassermann was negative. Renal function (phenol-sulphon-phtalein) test 75%. Blood urea and sugar were normal. Blood culture and repeated examinations for malaria were negative. Basal metabolism rate plus 7%. Urine was negative, including the examination for urobilin. X-ray of chest was negative. Roentgenograms of the gastro-intestinal tract and a cecum enema disclosed nothing remarkable, except for a moderate degree of spasticity of the descending and pelvic colons.

A temporary diagnosis of a toxic infectious psychosis with an unknown focus of infection was made.

Ten days after admission the patient was circumcised. The temperature continued to fluctuate between 99° F to 102.6° F. More frequently it was near or at a 100° F in the mornings and 102.1° F in the afternoons or evenings, the leukocyte count rose up to 16,000. Disorientation, insomnia, memory defects and mild apathy persisted. Patient was not quite certain that he was sick.

Sixteen days after admission his buttocks appeared mottled with areas of bluish discoloration, an area of deep induration and slight redness appeared on the right buttock about 5 cm from the anus. Blood examination on that day showed Haemoglobin 70%, W B C 24,000 with 90% polymorphonuclear leukocytes. A diagnosis of ischio-rectal abscess was made and next morning the patient was operated upon under ether anesthesia.

About 100-150 cc of sanguino-purulent material was evacuated. A probe introduced into the sinus reached the hollow of the sacrum. A culture of the pus yielded a streptococcus.

A few hours after the operation the temperature was 99° F and after that it fluctuated between 97° F-98° F. The patient's appetite improved almost immediately, he appeared more cheerful, his irritability diminished mark-

edly, he would retain for several hours the name of the physician, previous to the operation he was unable to repeat names immediately after they were given.

Three days after the operation his Haemoglobin was found to be 60% with 4,000,000 R B C and 8,000 W B C, of which 74% were polymorphonuclear leukocytes.

In view of the anemia and failure to gain in weight (he weighed 109 lbs at that time), the patient was transfused within a week after the evacuation of the abscess, 850 cc of blood were used.

Four hours after the transfusion the temperature rose sharply to 105° F. This was accompanied by a dramatic recrudescence of the psychotic picture. The patient displayed a great deal of psycho-motor activity, he jumped out of bed, urinated and defecated around the room, later he had no recollection of his behaviour, nor could he recall for a long while the transfusion during which he was quite clear mentally. The temperature fell gradually and within two days it reached 97° F. A moderately severe herpes labialis was observed at that time. The temperature thereafter remained subnormal or almost normal.

The mental symptoms disappeared. His physical condition improved considerably. He soon weighed 138 lbs, having gained about 38 lbs in seven weeks. The sinus of the ischio-rectal abscess which for a time was kept open with a drain, was healing satisfactorily, only a scant serous exudate coming from it. A short time before he left the hospital he had a nocturnal emission which caused no discomfort. Heretofore erections were incomplete and painful on account of the phimosis. Proctoscopic examination was negative, it was noted that the mucous membrane of the rectum appeared slightly anaemic. Blood examination showed Haemoglobin 85%, R B C 5,000,000, W B C 6,500. He was discharged as recovered two and a half months after admission.

Two weeks after he left the hospital, the patient was married. When seen six weeks later, he had no complaints. The abscess wound was healed, he weighed 156 lbs and was back at his usual work. He continues to be well at present.

\* \* \*

Certain points of interest are presented by this case.

In the family we observe a strong religious trend and a number of individuals, including the patient, who remained unmarried. In the patient are found certain anomalies of development, such as a congenital deformity of the small toes, a feminine carrying angle, a feminine distribution of pubic hair and an extreme phimosis. Circumcision, under the circum-

## A PSYCHOSIS CAUSED BY A LATENT FOCUS OF INFECTION\* (ISCHIO-RECTAL ABSCESS)

Bloomington Hospital, White Plains, N Y

THE patient, a departmental chief of a textile mill in New Jersey, was a bachelor of 47 when admitted to Bloomingdale Hospital

He came to the United States 25 years ago from Germany. His family is German on both sides. Father died of pulmonary tuberculosis at the age of 45, when the patient was one year old. Mother was living and well at 90. One maternal uncle suffered from a chronic psychosis and died in an institution for mental disorders. Another maternal uncle remained unmarried and died at 90. Two living sisters are unmarried at 53 and 55 respectively. The patient is the last of eight children. There is a strong trend of Lutheran fanaticism in the family.

The patient's occupation required the minute examination of the raw material as well as the completed fabrics, strong light and magnifying glasses were used. He has been engaged in this work for fifteen years, and as a result his vision became slightly impaired. He did not drink during business hours, but for many years he was in the habit of drinking several glasses of wine daily, he would do this at home, without company, or at his club in company of his associates and friends. As a rule he would become only mildly intoxicated. He has smoked moderately since the age of 25. Fifteen years ago he is said to have had some bladder or kidney trouble, but he was not long under treatment. Since that time he has been well till the onset of the present illness. His average weight was 152 lbs.

Four and a half months before admission he contracted a cold, soon after his "back teeth" were extracted. He felt below par for about two months and finally had to take to his bed. Herpes labialis was observed, his dejecta were examined and he received some vaccine treatment, but without relief. He appeared apathetic and did not seem much concerned about getting well. Two weeks later, i.e., about two months before admission he showed the first signs of mental disorder (forgetfulness and confusion). He asked for his medicine immediately after he had taken it, he dressed and said he was going out for a walk, he spoke of a hail storm which he supposed had occurred the day previous. He ran a temperature which did not subside and finally, one month before admission to Bloomingdale his physician moved him to the private

pavilion of a general hospital in New York City.

The patient complained of constipation and pain in the region of the hips. The physical examination at that time was recorded as negative except for an enlarged liver. The temperature showed daily afternoon rises to 101°-102° F. The leukocyte count varied from 14 to 21 thousand with 80% to 85% polymorphonuclear leukocytes, haemoglobin at that time was recorded as 80% with 4,400,000 R B C. Fluoroscopy of the chest and roentgenograms of the gastro-intestinal tract yielded negative findings. Blood culture, the Wassermann reaction of the blood and spinal fluid, the Widal test, examination of the feces—were all negative. Blood urea, creatinin, uric acid, sugar and CO<sub>2</sub> combining power, were normal. Urine examination was negative except for an occasional trace of albumin. The patient weighed 128 lbs, i.e., he was 24 lbs below his usual weight.

The patient became delirious, sleepless and increasingly restless, he was irritable, disturbed and difficult to manage. He was taken to Bloomingdale after a month's stay in the General Hospital. The patient's physician considered it to be a case of an alcoholic psychosis and suggested that the "origin of the fever might be in the liver together with obstinate constipation."

On admission to Bloomingdale Hospital, the patient appeared chronically ill, pale, dehydrated, 28 pounds underweight. The temperature was 99.5° F. The pulse 92, respirations 28. Eye grounds negative. Chest was negative. Blood pressure 103/70. Radial arteries not palpable. Liver not enlarged. Spleen not felt. Abdomen boggy, deep reflexes very active, both abdominal and right cremasteric reflexes were absent. Rectal examination negative. Prostate not enlarged. Both small toes were overriding their fellows—a congenital deformity. The carrying angle was feminine. Pubic hair of feminine distribution. Genitalia quite small. Little more than the meatus could be seen, the glans penis being concealed by an extreme phimosis.

The patient was partially disoriented as to time, place and person, he could not explain why he was brought to the hospital and referred vaguely to his genitalia as being in need of treatment. He was a little restless, abstracted, unable to keep up a sustained conversation, using German and English words to make up one sentence. He seemed evenly dull and satisfied. He said he felt very strong,

## RADIUM THERAPY IN TUBERCULOSIS CERVICAL ADENITIS

By G ALLEN ROBINSON, M.D., NEW YORK, N.Y.

From the Radium Department, Manhattan Eye, Ear and Throat Hospital

**T**UBERCULOSIS of the cervical lymph nodes, according to Fraser, occurs by way of the blood stream in about 10 per cent of the cases, and through lymph channels from a local focus in approximately 90 per cent of the cases. Scattered, haphazard, and often coincident appearance of multiple diseased nodes suggest a blood infection. In the local development of a tuberculous lymph node the disease remains for a long time localized to the node, or those immediately surrounding it, thus suggesting a lymphatic infection, and more especially if the affected nodes lie in a lymphatic connection with such obvious areas of absorption as the tonsils. Tuberculous adenitis is far less common now than two decades ago, and would appear to be due to the better oral hygiene, early tonsillectomy and adenectomy, and a better milk supply.

Early surgical removal of localized tuberculous lymph nodes is a conservative procedure, but, according to Hanford, extensive dissection must be tempered with an eye to the ultimate appearance of the neck, and safety to patient and surrounding structures. The aim of treatment is a good cosmetic result which shall be permanent. In 75 per cent of the cases reported by Smith and Hopkins, complete excision was impractical,

or impossible. A clinical cure was obtained by roentgen-ray treatment in 12 of their 21 cases. Six were markedly improved, two showed only slight improvement, and one died of unknown cause. Amundsen's results with roentgen-ray treatment showed 81 per cent cured of 32 patients with simple enlargement of the glands, 49 per cent of 32 with periadenitis in addition, and 77.4 per cent were cured of the 53 with suppuration and fistulas in the glands. The total cured thus averaged 66 per cent, and recurrence was observed in 4 per cent. All were reexamined from two to nine years since treatment.

Of fifty cases of tuberculous adenitis treated by Gosse with radium, 37 were cured, 9 improved, 3 not improved, and one dead. Tischy states that reexamination, two years or more later, showed recurrence in 74 per cent of 39 cases of tuberculous glands treated by operative measures, but there was a recurrence in only 11 per cent of 27 that had been treated by raying. In another group of 8 operative, and 25 rayed cases, the percentage of recurrences was 75 for the former, and 12 for the latter. All were selected cases, with enlarged or softened glands, but no fistulas.

Fig I Cervical Lymph Nodes (from Toldt)

Fig II Case 24, "J," showing suppurating sinus following recent incomplete operation.

stances, was indicated as a matter of simple hygiene. In this case, however, the phymosis was an important factor in the life of the individual in that it was disabling as far as sexual function was concerned. It has been observed that conditions of this kind, especially in individuals with a suggestion of feminine make-up, are amongst the causative factors of alcoholism. In the light of these considerations, circumcision was an indication of great medical importance.

As to the ischio-rectal abscess, there is room for speculation with regard to its primary cause. It would also be of interest to investigate, if possible, into the reasons why it was that a number of very severe symptoms had come into evidence such a long time before the diagnosis of ischio-rectal abscess could be made. Such speculations, however, are outside the scope of this communication.

A perusal of the literature failed to disclose a similar case. Faran and la Silvera<sup>1</sup> tell of a case which showed psychotic manifestations a long time before it was discovered that a suppurative phlegmona in the ilio-lumbar fossa was the underlying cause. It must be stated that whatever the underlying cause, an empyema, a renal calculus, a deeply seated abscess or a systemic infection, the symptom-complex of the psychosis remains more or less the same. It is well defined and allows of little or any mistake in diagnosis.

Bonhoeffer<sup>2</sup> formulates the following diagnostic suggestion to serve as a guide in the recognition of the whole group of infectious psychoses. The patients, he says, lose the feeling of being ill and enter a state of mild euphoria.

Liebermeister, who was the first to describe the exact symptomatology of infectious psychoses, recognizes three clinical stages.

In the *first prodromal stage*, the patients are still oriented as to time, place and person, the first cerebropathic signs can be observed, headaches, oversensitivity to light and mild noises, psychic irritability, slight motor restlessness, vivid dreams, a tendency to become frightened in sleep, when awake, the patients have the feeling of an uncontrollable rush of thoughts, these latter present usually actual memories of certain situations of the patients' lives, the memories show a tendency to stand out as plastic visions, there is pressure of speech, the patients experience a difficulty in finding the right words. The first memory lapses come into evidence.

In the *second stage* the patients have optic illusions. As soon as they close their eyes,

they have hypnagogic hallucinations, quite frequently they see themselves travelling on high seas, or flying in the air, or falling. As soon as they open their eyes they come to again. Hence fear of falling asleep and insomnia. The patients become disoriented. If they do at times regain consciousness of reality they do so only after a very taxing effort of attention. They speak or mutter in response to their hallucinations, they laugh or cry out spontaneously, they suffer from the discomfort of motor restlessness. The feeling that gradually enters the state of coma.

In the *third stage* flight of ideas predominates. Reminiscences become plastic, as if real. Motor restlessness decreases gradually. The patient becomes ataxic, then stuporous and gradually enters the state of coma.

August Hoch<sup>3</sup> in this country studied the organic deliria and reconstructed a symptom complex somewhat similar to this which incidentally was observed by the clinicians of two centuries ago.

Thomas Sydenham was one of the first to point out the psychotic manifestations which accompany or follow severe malarial infections.

It is of interest to note that the great dearth of institutions for mental disorders in the middle of the nineteenth century was partly responsible for the fact that the psychiatrists of those days (Esquirol, Martini, Georget, Burrows and others) considered the infectious psychoses as belonging to the field of general medicine. Jacobi was the first to consider them as within the competence of the psychiatrist.

Our case is peculiarly illustrative of the classical syndrome and reminiscent of the argument of three-quarters of a century ago, except that the dearth of hospitals for mental disorders is not as great at present.

The case suggests that it is rather unwise to draw a strict line of demarcation between these two branches of medicine. Such a demarcation tends to turn the psychiatrist away from the use of our medical equipment, and on the other hand it seems to deprive the general medical man from some clear cut concepts which ought belong to his armamentarium.

## RADIUM THERAPY IN TUBERCULOSIS CERVICAL ADENITIS

By G ALLEN ROBINSON, M D, NEW YORK, N Y

From the Radium Department, Manhattan Eye, Ear and Throat Hospital

**T**UBERCULOSIS of the cervical lymph nodes, according to Fraser, occurs by way of the blood stream in about 10 per cent of the cases, and through lymph channels from a local focus in approximately 90 per cent of the cases. Scattered, haphazard, and often coincident appearance of multiple diseased nodes suggest a blood infection. In the local development of a tuberculous lymph node the disease remains for a long time localized to the node, or those immediately surrounding it, thus suggesting a lymphatic infection, and more especially if the affected nodes lie in a lymphatic connection with such obvious areas of absorption as the tonsils. Tuberculous adenitis is far less common now than two decades ago, and would appear to be due to the better oral hygiene, early tonsillectomy and adenectomy, and a better milk supply.

Early surgical removal of localized tuberculous lymph nodes is a conservative procedure, but, according to Hanford, extensive dissection must be tempered with an eye to the ultimate appearance of the neck, and safety to patient and surrounding structures. The aim of treatment is a good cosmetic result which shall be permanent. In 75 per cent of the cases reported by Smith and Hopkins, complete excision was impractical,

or impossible. A clinical cure was obtained by roentgen-ray treatment in 12 of their 21 cases. Six were markedly improved, two showed only slight improvement, and one died of unknown cause. Amundsen's results with roentgen-ray treatment showed 81 per cent cured of 32 patients with simple enlargement of the glands, 49 per cent of 32 with periadenitis in addition, and 77.4 per cent were cured of the 53 with suppuration and fistulas in the glands. The total cured thus averaged 66 per cent, and recurrence was observed in 4 per cent. All were reexamined from two to nine years since treatment.

Of fifty cases of tuberculous adenitis treated by Gosse with radium, 37 were cured, 9 improved, 3 not improved, and one dead. Tischy states that reexamination, two years or more later, showed recurrence in 74 per cent of 39 cases of tuberculous glands treated by operative measures, but there was a recurrence in only 11 per cent of 27 that had been treated by raying. In another group of 8 operative, and 25 rayed cases, the percentage of recurrences was 75 for the former, and 12 for the latter. All were selected cases, with enlarged or softened glands, but no fistulas.

Fig I Cervical Lymph Nodes (from Toldt)

Fig II Case 24, "J," showing suppurating sinus following recent incomplete operation.

Fig III Case 25, J S Recurrent post-operative tuberculous cervical adenitis

The three pathological types are the caseating, the lymphoid, and the fibrous. The caseating variety is the most common. Superadded pyogenic infection is often present, increasing the caseous material, producing periadenitis, and discharging sinuses. Radium in tuberculous adenitis should be considered as an adjunct to the other well-known measures employed in the treatment of tuberculosis. The foci of infection should be determined and eradicated, excessive strain and fatigue avoided, proper diet, fresh air and sunshine are essential.

Radium produces an inflammatory reaction in the tissues which hastens the healing of discharging sinuses, and causes a gradual shrinkage of the tuberculous lymph nodes. Many nodes, particularly those of the lymphoid type, will entirely disappear, while others remain as fibrous nodules. Healing occurs through a hayline change of general scarring, and sometimes with a deposit of calcium which is tightly encased in a fibrous capsule. Dr J C Mottram writes as follows: "The cellular changes which follow the irradiation of tuberculous lymphatic glands finally result in fibrosis. There is an early disappearance of the lymphocytes, which either disintegrate or are phagocytosed by macrophages. The lymphoid myeloblasts, except after large doses of radium, do not persist, and later may reform lymphocytes. The lymphoid follicle atrophies, only the central cells remain. The endothelial meshwork of the glands remains little altered, except for a great increase of fibrous tissue, so that the whole gland,

shrunk from the loss of lymphocytes and other cells, come to consist of narrow spaces lined with endothelial cells running through thick fibrous tissue. In this tissue the tubercles persist, more especially the giant cells, and here tubercle bacilli have been found persisting many months after radiation. It has been concluded from these appearances that the good clinical results are due to the creation of a site unfavorable to the growth of the tubercle bacilli, rather than to any direct action of the radiation on the bacillus. The dose of radiation given is always very much less than the lethal dose for the bacillus, nevertheless, a direct action on the bacillus may also be a factor, for the reason it is well known that sub-lethal doses of radiation effect a lowering of the virulence of bacilli."

#### TECHNIQUE OF RADIUM APPLICATION

There is no set rule for the treatment of these cases. The lymph nodes to be treated are carefully located, and palpated, and with a dermatographic pencil areas are mapped out on the overlying skin. Incision or aspiration of the pus and caseating material is indicated before radiation. A large firm mass will require more radiation, and a deeper penetration than soft superficial nodes. In most cases 100 mgs radium element in three or four tubes strapped to a block of

Fig IV Case 25, J S End result after radium treatment

balsam wood 5 by 7.5 by 3 cm for a period of 15 hours, will cause a rapid regression of the nodes. The gamma rays are employed and each square centimeter skin surface receives 40 mg hours at 3 cm distance, which is approximately one-half an erythema dose. Full erythema doses should be avoided, because of the possibility of latent skin atrophy. The treatments are repeated at monthly intervals, and, as a rule, five or six applications are necessary.

#### SUMMARY

In the series of 25 cases of tuberculous adenitis treated by radium, 18, or 72 per cent, are clinically well, two are dead, five improved, but still have active nodes. Radium, if properly used, is a safe procedure, and gives a high percentage of cures. Unless sinuses were present, no scars are left. Radical operation is contraindicated, because of the tendency to recurrence and the disfiguring scars.

Fig V Radium Block applied to lymph nodes of neck.

#### REPORT OF CASES

No.	Name	Age	Sex	Examination	Duration of Disease	No. of Treat.	Duration of Treatments	Total No. of Mg Hrs.	Duration of Observation	Result
1	C.D.	25	F	Firm mass 4 by 3 by 2 cm. in left submaxillary region	1 yr	5	7 mos	3,500	3 yrs.	Satisfactory
2	V.M.	38	M	Large firm mass 6 by 6 by 4 cm. in right neck.	2 mos	5	8 mos	6,240	2 yrs	Satisfactory
3	A.F.	27	M	Hard mass of nodes 6 by 8 by 4 cm. in left submaxillary region with a chronic suppurating sinus	4 yrs	5	18 mos	14,650	2 yrs.	Improved, mass one-half the original size. Sinus healed, still under observation.
4	P.R.	25	M	Large, hard mass 8 by 5 by 3 cm. in left submaxillary region. Had several low voltage X-ray treatments in Germany 3 yrs previously. Skin shows considerable atrophy	4 yrs	1		3,200	1½ yrs.	Satisfactory
5	H.K.	10	M	Firm discreet mass 4 by 4 by 6 cm in left submaxillary region	10 mos	9	2 yrs 9 mos	14,000	3 yrs.	Satisfactory
6	P.M.A.	33	F	Numerous scattered nodes, both sides of neck have increased in size during the past six months. Numerous incisions	8 yrs	7	15 mos.	13,400	3 yrs 6 mos	Satisfactory. Few fibrotic nodules remain.
7	M.G.	22	F	Firm swollen nodes 4 by 3 by 1 cm. anterior angle of neck. Numerous discreet swollen nodes 1 to 3 cm. on both sides of neck.	4 yrs	2	6 wks	2,800	3 yrs.	Satisfactory

## REPORT OF CASES—Continued

No	Name	Age	Sex	Examination	Duration of Disease	No of Treat.	Duration of Treatments	Total No of Mg Hrs.	Duration of Observation	Result
8	V McA.	19	F	Numerous scattered nodes both sides of neck.	12 mos	2	5 wks	3,100	2 yrs. 3 mos	Satisfactory
9	A. D.	11	F	Large discreet lymph nodes both sides of neck. Deep sinus left submaxillary region. Mother has pulmonary tuberculosis	1 yr	6	2 yrs 9 mos	13,700	3 yrs. 6 mos	Satisfactory
10	M F	42	F	Several discreet nodes in left side of neck 2 by 4 cm in diameter 14 low voltage treatments 2 yrs before. No atrophy of skin.	6 mos.	1		1,120	3 yrs.	Satisfactory Fibrous nodules remain.
11	H. F	5	M	Suppurating nodes both sides of neck. Incisions have been made	3 yrs. 6 mos	6	2 yrs. 6 mos.	5,900	2 yrs 6 mos.	Improved. A few nodules remain.
12	N S	16	F	Large diffuse soft nodes right side neck. 6 lesions on face ulcerated, from 2 to 4 cm in diameter	3 yrs	9	2 yrs 3 mos	1,400	4 yrs	Improved face lesions healed. Mass in neck is smaller
13	H H	27	F	Colored, diffuse, swollen, tender nodes both sides of neck. Loss of weight. Advanced pulmonary lesions	1 yrs	6	1 yr	14,400	2 yrs 6 mos	Died pulmonary tuberculosis
14	D N	25	F	Diffuse, large, hard nodes both sides of neck. More marked on left. Incipient pulmonary tuberculosis	4 mos	6	2 yrs	11,000	2 yrs	Small fibrous mass left side of neck. Lungs clear after six months treatment in Santa Fe, N. M. Has gained 16 pounds in weight.
15	L. R.	18	F	Previous operation 5 yrs ago. Right side of neck fairly soft 10 by 10 by 4 mass. In submental regions mass 4 by 4 by 2 cm.	6 yrs	4	5 mos	13,400	1 yr	Satisfactory
16	E. B	22	F	Entire right side of neck diffusely infiltrated, with a deep suppurative sinus anteriorly	6 mos	2	2 mos	3,300	1 yr 9 mos	Satisfactory, few fibrous nodules. Sinus healed.
17	A G.	27	F	Dissection lymph nodes right side of neck 10 wks previously. Swollen mass right submaxillary region 8 by 6 by 3 cm with chronic suppurative sinus present.	4 mos	3	6 wks	2,170	2 yrs 9 mos.	Satisfactory
18	L. H.	20	F	Previous excisions in France. Diffuse soft nodes both sides of neck with several suppurative sinuses	5 yrs.	10	5 yrs	3,065	7 yrs.	Satisfactory

## REPORT OF CASES—Continued

No.	Name	Age	Sex	Examination	Duration of Disease	No. of Treat.	Duration of Treatments	Total No. of Mg Hrs.	Duration of Observation	Result
19	D F	20	M	Excision 5 yrs previous, lymph nodes right neck 10 by 7.5 by 4 cm	3 yrs	9	3 yrs	11,300	5 yrs 3 mos	Satisfactory A small fibrous mass remains
20	J L.	14	M	Previous excisions Several confluent nodes forming ulcerating mass in right neck 12.5 by 5 by 3 cm	3 yrs	17	6 yrs.	20,530	6 yrs	Improved, had relapse after 2 years A small mass remains which may cause trouble.
21	M. G	26	M.	Previous excisions, extensive suppurating node involvement right neck. Evidence of healed tuberculous right upper lobe.	2 yrs	12	3 yrs. 6 mos	24,260	3 yrs 9 mos.	Satisfactory, fibrous nodules remain. No active pulmonary tuberculosis
22	M. T.	8	F	A & T operation 4 yrs ago Complete cervical adenectomy on right side 2 yrs. later Swelling behind right tonsil pillar Several swollen lymph nodes 1 to 3 cm in diameter	3 yrs	2	6 wks	2,250	2 yrs 3 mos.	Satisfactory
23	P O	12	F	Colored. Previous excisions, extensive suppurating nodes both sides of neck. Right eye tuberculous	1 yr	6	1 yr	8,950	2 yrs 4 mos	Satisfactory Fibrous nodules remain. Eye condition healed.
24	J A.	16	M	Recent operation right side of neck, extensively involved discharging sinus	1 yr	8	1 yr	4,950	2 yrs 7 mos	Satisfactory
25	J S	43	M	Entire left side of neck a huge suppurating mass of lymph nodes Previous aspirations	3 yrs	10	2 yrs	35,000	7 yrs	Neck healed. Five years later patient died of influenza.

## THE EVOLUTION OF MEDICAL SOCIETY METHODS

Physicians are rapidly acquiring a civic consciousness and are developing methods by which they may perform their civic duties through their spokesmen in the county societies. It is interesting to note the evolution of the civic activities of medical societies in the several counties and states. One county society, for example, conducts free clinics for immunizing children against diphtheria; another sends the children to the private offices of the doctors, while still another does the immunizations through clinics in which the at-

tending doctors are paid from Red Cross funds. Comments on these various methods are found in the account of the Tri State Conference which is reported on page 733 of this issue.

It is noticeable that the more the leaders of medical societies investigate the calls to civic work, the more insistent are they that the members of the medical societies of the county, states and nation shall assume the leadership in all lines of public health work and the practice of civic medicine.

## STATE MEDICINE

State medicine, or the treatment of individual cases of sickness by the Government, has been a favorite subject of condemnation by presidents of State Medical Societies in their annual addresses, and justly so. But while pure state medicine is undesirable from every point of view, yet certain functions in medicine must be conducted by the community. What those functions are may be clearly seen on an analysis of the present medical situation.

Physicians have always been willing to treat the poor without remuneration, but through ignorance or prejudice it is often impossible to secure adequate cooperation in following out the advice given. Every physician has frequently gone through the disheartening experiences of spending hours on patients who fail to cooperate in their administrations. The temptation is always strong for the doctor to cease trying to give advice unless the patients think enough of it to follow it and pay for it.

The failure of patients to follow advice is popularly ascribed to financial conditions, and the charge is sometimes made that doctors can bring about cures if they are paid to do so. The response to this popular belief is the proposal that the state should provide the medical advice at public expense upon the theory that doctors paid for full time service will give the best medical advice, and that the patients will follow it effectively. But experience has abundantly demonstrated that state medicine, or free advice, is a failure for a reason that is evident when it is considered in its logical relation.

There are two principal reasons why people fail to profit by medical advice. The first reason is *economic*, and includes such conditions as poverty, housing, occupations, etc. This group of reasons is *environmental* and deals with conditions outside of the body.

The second reason is inherent within the patient, and is his *personal characteristic*, or temperament, either openmindedness or prejudice, bravery or fear, backbone or moral weakness. No amount of financial aid can supply the brains, and will power that are often needed for the cure or prevention of sickness.

Economic relief does not settle problems of medicine any more than they settle those of morals and religion. The church no longer considers that almsgiving affords more than temporary relief. It does not improve the morals of the recipient. It not only fails to arouse an aggressive spirit of selfhelp, but on the contrary it encourages laziness and dependency.

The modern method of dispensing charity

is based on education and inspiration, in order to arouse reliance and self-support.

The same principle applies to medical relief and advice. The physician can offer medicine to a patient, but he cannot make the patient take it. He can advise early bedtime hours for an ill nourished child, but he cannot keep the parents from taking the child to the evening movies. Free advice and State medicine will not supply the intelligence and backbone on which strength and vigor are founded.

Medical aims being only a temporary makeshift, there remains the alternative of instilling knowledge and moral stamina into the people. This is the object of health education. This is the collective work of the community. It is general and covers all health topics. The individual physician cannot do it with any degree of effectiveness, for his class would number from 500 to 1,000 persons, that being the average number that a physician serves. Health education is the work of departments of health and education, and of voluntary organizations, such as public health nursing organizations, parent teachers associations, and anti-tuberculosis societies.

State medicine finds its own peculiar field in medical education. Nearly all physicians are agreed on that point, but they disagree on some of the details of how it should be carried out. One point of disagreement is that concerning clinics conducted for demonstration purposes. The physicians of Newburg for example, agreed to conduct a demonstration whose object was to immunize all the children of the city against diphtheria with the expectation that in succeeding years parents would have it done by their family doctors. The physicians of Schenectady agreed to the principle of medical education of the people at public expense, but insisted that the anti-diphtheria immunizations should be done in their offices as a part of their private practice. The physicians of Cambria County, Pennsylvania also agreed that the education of the people should be done at community expense, but they gave the immunizations for pay that was supplied by the Red Cross. These demonstrations were described and discussed at the Tri-State Conference of officers of the Medical Societies of the States of New York, New Jersey, and Pennsylvania that is reported on page 733 of this Journal. The encouraging feature that is common to the work in all the communities is that the physicians agreed that health education was a state or community function.

There was also an agreement that physicians are charged with the obligation to en-

courage health education. The medical leaders felt that all physicians should be willing to forego immediate pay and to give diphtheria immunizations free as a part of the educational work of the community.

The recent growth of the sense of civic duty of physicians to assume the leadership in all things medical has been remarkable. Health is a peculiar commodity in that it is

essential for every person in a community. Physicians are organized into County, State and National societies, which are like churches. Some physicians are high priests of health, more are deacons and elders, while all can be members and supporters of the great ideal of securing perfection physically just as the church stands for perfection morally.

## PHYSICIAN REFUGEES IN THE UNITED STATES

It is hard to realize that in the ranks of the medical profession are hundreds of men and women looking for work. Many of these are foreigners who have come to the United States to get away from the depressing conditions in Europe. They come, full of hope and ambition, sometimes with excellent equipment, professionally and personally, but because of lack of influence, perhaps on account of unfamiliarity with our language, the discouragement they meet on every hand is tragic. This is particularly true in the case of women doctors who come here. There have been quite a score of women M.D.'s during the past year who have come to the New York Academy of Medicine with nothing but their diplomas in their hands and hope in their hearts. Russian

for the most part, are these pilgrims, but other countries, especially Austria, are also represented. The Academy tries to find positions for these applicants, but when a doctor has been in practice for five, ten, fifteen years, he or she is not quite fitted to start afresh with an internship, and yet such are almost the only openings available. The cooperation of hospitals in keeping the Academy of Medicine, through its Bureau of Clinical Information, advised as to present and future vacancies would be of immense help. If individual doctors would let the Bureau know of any opportunities, anywhere, which might solve the problem of earning a livelihood for some brother doctor, the encouragement would be of the greatest value.

## LOOKING BACKWARD

### THIS JOURNAL TWENTY-FIVE YEARS AGO

The American Medical Association. *The New State Journal of Medicine* for July, 1902, contains an account of the annual meeting of the American Medical Association in Saratoga. The reports showed that the Association then had 22,000 members. The membership dues were apparently two dollars, for \$46,505 was reported as the amount collected during the year.

The JOURNAL produced an income of \$113,740, all of which was probably from advertising. The Association had about \$91,000 assets in cash and bonds. Consideration was being given to the purchase of a site for a building to house the Association.

The question of the relation of the societies of the counties and states to the A. M. A. was extremely loose. The account says:

"On March 8 the secretary of the New York State Medical Association forwarded a list of 161 names of members of the American Medical Association residing in New York who were not members of the New York State Medical Association or any of its branches, and asked that

these be dropped from the roll of members of the American Medical Association. I declined to take this action, because I could find nothing in the constitution and by-laws authorizing me to do so.

"There has been no way of keeping in touch with such matters in the past, since there has been no close relationship between this Association and its subordinate branches and no attempt to report to the higher body on the part of the lower. In the future, when we became organized according to the proposed plan, it is presumed that a systematic method of reporting by the county society to the state society, and by the state society to the Association, will be adopted and carried out. The present conditions are certainly not satisfactory. We have had on our books as members until quite recently, and probably have yet, men who are the veriest quacks and the most notorious advertisers in the country. This has occurred from the fact that it is impossible to keep in touch with each individual member unless it is done systematically by such reporting as it is hoped will soon be adopted."

# MEDICAL PROGRESS

**Prickly Heat as a Mycotic Dermatitis**—An editorial writer in the *Journal of Tropical Medicine and Hygiene*, May 16, 1927, xxx, 10, states that as regards the pathology of prickly heat the views of Pollitzer have usually been accepted, namely, that its production depends upon the noncornification of the cells of the stratum corneum, the cells of which, sodden by constant perspiration, swell and obstruct the orifices of the sweat glands and thus lead to an accumulation of fluid in the ducts. According to this view the condition is a form of malaria. Recently Smith, studying the disease in Lagos, found that areas of prickly heat presented scaling, and microscopical examination of the scales, after treating with caustic potash solution and staining by Gram's method, revealed the presence of mycotic bodies which he considered to be the causative fungus of the disease. A study of the morphological, tinctorial, and fermentative reactions of these fungi indicates that they belong to that class of the *Fungi imperfecti* known as *Monilia*, and comprised within the *balanica* and *rosca* varieties of the class. By inoculation of a culture of these monilias on the human skin a lesion is obtained which is comparable to prickly heat in an aggravated form. A monilia, identical with that used for inoculation, can be demonstrated in the scales and obtained from them in culture. Further, the monilia isolated from the lesion produced by experimental inoculation will, on reinoculation, produce a similar epidermal lesion. Finally, the presence of a Gram-positive yeast-like fungus can be demonstrated in sections of the horny epithelium of the roofs of vesicles or postules and in the superficial parts of the hair follicles of the experimental lesion. The logical deduction from these investigations is that prickly heat is a dermatitis of mycotic origin, and that the casual microorganism belongs to the monilia group.

**Severe Forms of Pregnancy Toxicosis**—H. Küstner describes certain forms of pregnancy toxicosis, some being quite masked as other affections. One woman for example appeared to be suffering from gallstone disease, probable empyema of the gall-bladder, great enlargement of the liver with jaundice, high temperatures, and likelihood of sepsis. Interruption of pregnancy was indicated although not with the supposition of toxicosis. But no sooner was the uterus emptied than all of the symptoms rapidly subsided. In 48 hours the liver had become normal in size. The only symptoms

which had at all suggested toxicosis were albuminuria and casts and a high blood pressure. Another patient showed obstinate vomiting but aside from this symptom the diagnosis pointed to either pyelitis or paranephritic abscess. The liver was enlarged and tender and there was much albumin in the urine but no casts. As the patient went from bad to worse, the incessant vomiting threatening death by exhaustion and inanition, the uterus was emptied and a few days later all symptoms had disappeared. Cases of this type differ notably from ordinary pregnancy-kidney and eclampsia on the one hand and from the more or less mild cases in which one organ bears the brunt of the intoxication. To account for them the author advances the view that the vegetative nervous system is singled out for attack. These cases develop late in gestation although there may have been hyperemesis from the first. The indication is plainly to empty the uterus and thereby eliminate the source of the poison—*Muenchener medizinische Wochenschrift*, March 25, 1927.

**Purification of Sewage-Contaminated Waters by Minimal Doses of Sodium Hypochlorite**—E. Techouyeyres and Mlle. Pillement refer to the method introduced during the war at Verdun by Bunau-Varilla for making infected water potable for the troops and which was sometimes termed "verdunization." The hypochlorite was introduced in such small quantities as to be imperceptible to the taste and the mixture took place automatically through the act of pumping. The presence of a decimilligram of the salt to a liter of water thoroughly disseminated by energetic stirring was sufficient for the destruction of all germ life. Since the war the same method has been used by health officers with polluted water at Reims, Carcassonne (typhoid endemic), Monte Carlo, and other places. Recently it has been attempted to disinfect actual sewage water before it can contaminate the basins into which it discharges. The tests were *in vitro*, sewage being submitted to the action of the hypochlorite in vessels of 100 c.c. capacity. Agitation was effected by the centrifuge driven by an electric motor. Controls showed that without thorough agitation the minute quantity of sodium hypochlorite was insufficient for purification, but when it was well stirred in, the sterilization of the sewage was complete. This preliminary work will in time be succeeded by actual attempts at disinfection of liquid sewage—*Bulletin de l'Académie de Médecine*, March 22, 1927.

**Progress in Medical Climatology.**—Franz Baur, apparently not a medical man himself, discusses this subject exhaustively in the *Klumsche Wochenschrift* for March 12, 1927. Progress in this field must have a double source, the first from medicine, and especially physiology, and the other from meteorology. Physiology has recently shown exhaustively the effects of the high sun on the human organism. The red and the shorter waves of the ultra-red rays have the deepest penetration beneath the surface of the body and at a depth of 25 cm. the tissues are more warmed in a given time than the surface. We now know that it's not alone the invisible rays that exert therapeutic activity, for some of the visible rays have the same properties. The effects of the solar rays must in fact be studied *in toto*. New methods have been evolved to measure the solar radiation intensities. The height and duration of the rays alike enter into computations and it is possible to measure the total intensity of radiation for a given locality over a stated time, so that climate becomes a quantitative science. The unit of measurement represents the total amount of calories for each square centimeter of surface, and the number of such units varies from such low figures as 1,227 for the winter months up to 30,380 for the summer months. A new method of measuring the ultraviolet ray intensity by means of the cadmium cell throws a further light on climate. The study of humidity has been similarly advanced with especial reference to the normal temperature of the body, and some older figures have been revised, the amount of vapor in the expired air being now placed at about 78 per cent. each cubic meter of expired air containing 33.3 gms. of aqueous vapor.

**Autopsies upon Jews and Gentiles.**—Writing in the *Boston Medical and Surgical Journal*, May 5, 1927, cxcvi, 18, Julius Gottlieb reviews the Talmudic literature concerning autopsy, from which he concludes that under no authority have necropsies been prohibited when good reason for their performance existed. With the failure to recognize the value of post-mortem examinations prior to the 19th century, the discussions relating to necropsies were based on purely sentimental considerations. The Jewish laity is generally of the opinion that autopsies are prohibited. It is conceivable that if the actual facts were brought to the attention of the Jewish people a great deal of the opposition would thereby be eliminated. Ginsberg of the Jewish Theological Seminary says, "About a century ago, because of the developments in modern medicine scholars began to discuss the question of autopsies and decided against them, which opinion is now considered authoritative by those who adhere strictly

to Rabbinic law." He is, however, of the opinion that sooner or later the rigor of the law will have to be essentially modified. Gottlieb thinks that if this question were formally brought up before a proper Jewish representative body, favorable action would result. He suggests that the Jewish press be solicited to cooperate by granting space in its columns for the dissemination to the Jewish laity of information which will facilitate the breaking down of the present attitude against autopsies.

Elliott P. Joslin, in the same issue of the *Boston Medical and Surgical Journal*, states that in twenty-eight years of the practice of medicine he has had but one autopsy on the body of a Hebrew, though he has taken care of thousands of that race. Autopsies upon his patients have been of inestimable value to him and from them Jews and Gentiles have profited alike, though the former have contributed nothing. This is not fair or just, and he believes that if the purpose of the autopsy was properly understood Jews would contribute as much to the progress of scientific medicine in this line of research as they have so notably contributed to all other branches. Every other diabetic is operated upon before he dies, why then should not every diabetic be operated upon after he dies? An operation during life is attended with pain and is for the benefit of the individual, an operation after death is without pain and for the good of humanity. Joslin urges that old men and old women above all others should demand that autopsies be performed upon them, for the reason that in dealing with old people it is easy to think their troubles are due to old age and to cease to be aggressive in finding relief for their real complaints. Furthermore, the physician who knows that his method of treatment will be checked up by an autopsy will unwittingly take more pains with his patient. Every Jewish physician should arrange that a postmortem examination be made upon himself and one should take special pains in the families of Jewish physicians to secure permission for these examinations.

**Lymphadenitis Treated by Vaccino-therapy.**—Pierre Delbet supplements a communication published in 1923 on the tentative use of an auto-vaccine in lymphadenitis. During the interim he saw no patient with this malady until late in 1926, when one came to his clinic and was soon followed by a second. Both were subjected to autotherapy as follows: a portion of an affected ganglion was excised and after desiccation pounded into a pulp for injection. The results were startling. The first patient, a youth, developed adenopathy in the right groin five or six days after a suspected coitus. The lymph-nodes were slightly tender and became fused with one another and adherent to the skin. The entire mass was the size of a hen's egg while a

second agglomeration could be palpated in the iliac fossa. The injections caused no local reaction but the enlarged nodes, which had already showed some fluctuation, rapidly melted away. There were no traces save for the slight scar of the operating wound. The second case was somewhat different—a bilateral inguinal adenitis ushered in with fever. On one side the mass of glands was the size of the fist. Both required incision to give exit to pus with resulting fistulous openings. As there was no tendency to resolution the two masses were finally excised. All bacteriological examinations had been negative. Some of the nodes were left behind while the operation wounds continued to discharge freely. The injections were now employed, a pulp being made from some of the excised glands, and a course of five injections led to a complete recovery. In this patient some local reaction and fever were noted after the injections. The total number of cases treated in this manner is now five, all with success. Treatment by radiation and ultraviolet light was without result—*Bulletin de l'Académie de Médecine*, April 5, 1927.

**Casual and Unexpected Cures of Supposedly Incurable Skin Diseases**—Edward A. Blount (*Southern Medical Journal*, May, 1927, xx, 5), recalls that he once heard a distinguished French dermatologist remark, "once a psoriatic always a psoriatic," yet many patients have been cured of psoriasis. He cites as an instance an apparently hopeless case of this disease in which, to relieve the minds of those concerned, he prescribed large doses of strontium salicylate internally and an emulsion containing calamine and zinc externally. This patient was cured and never had a recurrence. Later he read of the intravenous use of salicylates, and began using a prescription consisting of lactic acid, acetic acid, salicylic acid, and liquor formaldehyde each 3 drachms, bichloride of mercury, 4 grains, in alcohol up to eight ounces. In addition he employed ultraviolet light, which should be successful in psoriasis, as this disease seldom occurs in those parts of the body exposed to the sun. Endocrine therapy is also at times useful in psoriasis. Blount also cites two cases of vitiligo associated with endocrine dysfunction in which the vitiliginous spots disappeared following appropriate endocrine therapy. A most unexpected cure of vitiligo occurred in a patient who had been treated in every other way unavailingly. While standing knee-deep in water in her bathtub, she switched on an imperfectly insulated electric light bulb, and caught the whole city voltage. She recovered from the shock within three weeks and was cured of the vitiligo. Needless to say, Blount does not recommend this heroic measure. Another unexpected result occurred in a patient with a geographical tongue, who was also a sufferer from an infected gall-

bladder. Intravenous injections of 31 grains of methenamine were given every twenty-four hours. Within six weeks the cholecystitis was well and also the tongue. In four cases of acne refractory to other methods of treatment a cure was effected with neoarsphenamine. In three of these the Wassermann reaction was negative and the patients were not informed as to the type of medication they were receiving.

**Hereditary Cancer**—Auvray discusses both familial and hereditary cancer although the history of a cancer family described by him ought to be classed rather as hereditary than familial. The student of cancer family geneology must have remarked that as a rule the morbid growths appear in any locality, even at times in some in which cancer is extremely rare, that there is no type of cancer, but all forms of malignancy are represented. The fact that with the appearance of cancer in new generations the patients tend to develop the disease earlier and earlier in life probably accounts for the fact that acute cancer may be largely represented in families. The author first describes two examples in which grandmother, mother, and daughter developed respectively cancer of the rectum, and cancer of the ovary. No other cases are mentioned in these families, so that we may speak of hereditary cancer, the type and location having been repeated in three generations. The law of progressive lowering of the cancer age seems to have been made good, for in the first family the ages were respectively 70, 65, and 54. In the other family the age of the grandmother is not given, but in the following generations it was respectively 55 and 27. It is not often that the medical man is fortunate enough to control three generations and it was made possible in this case only because Auvray succeeded to his father's practice and records. In the familial cancer history the author obtained his material from another practitioner, Guénot. In the first generation the father had what in all likelihood was cancer of the stomach, surely cancer in the abdominal cavity. Four children of the second generation died of cancer of the stomach, and of 12 children in the third generation four also have succumbed to the same disease. The fourth generation is thus far immune but the members are still quite young. Owing to constancy of type and location we should speak here of hereditary cancer—*Bulletin de l'Académie de Médecine*, March 29, 1927.

**Paget's Disease of the Nipple with Subjacent Canicular Epithelioma**—G. Barbier of Marseilles relates the case of a woman of 52 of excellent health who had borne and nursed four children now living and well. Five months before, she had first seen a lesion of the right areola at the nipple base—a minimal excoriation

which would heal under local applications but always reappeared quickly. A medical attendant had surmised the nature of the process, but a surgeon when appealed to declined to remove the breast. When seen by the author the lesion was still a crusted excoriation 6 by 4 mm. The nipple was depressed but not retracted and the somewhat fat breast seemed normal. A biopsy gave the diagnosis of Paget's disease and the breast was at once removed. There was nothing abnormal to the naked eye, but the microscope showed a canalicular epithelioma extending for a width of 7 or 8 mm. The breast itself showed chronic mammitis in evolution. This association of a superficial process with involvement of the subjacent canaliculæ has long been known to characterize Paget's disease. It explains the incurability of the superficial erosion and the ultimate involvement of the mamma. The author spoke of the erosion of the areola as "precancerous." In discussion Pautrier stated his belief that there was no precancerous lesions in Paget's disease but that from the first cancer was actually present. Milian has recently expressed the opinion that the lesion in the nipple infects the breast secondarily, his chief argument being that Paget's disease of typical appearance has been seen in such localities as the finger, the abdominal wall, and elsewhere where there is nothing analogous to a subjacent mammary gland. Darier referred to cases of Paget in which the breast is not involved and Milian spoke of a "pagetoid" epithelioma which is not a true Paget. The two opposed views seem irreconcilable, although recently attempts have been made to reconcile them—*Bulletin de la Société Française de Dermatologie*, March 3, 1927.

**The Precancerous Dermatoses**—Samuel Feldman discusses a group of dermatoses which are benign in their early stages, and may remain so for a long time, but ultimately a large percentage of them develop into cancer. By diligently watching and intelligently treating these lesions, cancer can be deprived of many of its victims. Foremost in this group of dermatoses are nevi, and especially the so-called soft verrucous nevi. Then there are the lentigos, dark brown or black spots about the size of a lentil which may result in general melanosis. The treatment consists of radium, x-rays, carbon dioxide snow, and endothermy, the last being by far the safest and most effective. Surgical procedure in these cases is dangerous unless a large area of healthy skin is removed with the lesion. All nevi whether brown or black, should be removed. Warts are important for the reason that some epitheliomata start in warty growths and should not be mistaken for warts. Special care should be exercised when a wart appears singly in a location where cancer is frequent, and on a base which predisposes to cancer

formation. Senile keratosis, although not extremely malignant, should receive attention. These keratoses may be removed by means of soft soap poultices or salicylic acid ointment and the destruction of the base of the lesion by monopolar endothermy. In the author's hand the x-ray has not given good results. Presenile dystrophy and xeroderma pigmentosum, which result from undue exposure to inclement weather in the case of the former and to sunlight in the case of the latter, should be destroyed as soon as they make their appearance and further exposure should be avoided. Leukoplacia, in mild cases, may be treated with arsphenamine, but if resistant to ordinary treatment, will heal readily under small doses of radium or x-rays. Very thick patches may be destroyed with monopolar desiccation, while beginning cancer requires removal with the endothermy knife. Paget's disease and Bowen's disease both demand radical removal, preferably by coagulation. Although radium and x-ray may be efficient in a number of cases, in the main they are not satisfactory. The fact must not be overlooked that cancer occurs in the site of old scars, ulcers, fistula, syphilitic gumma, and lupus. Occasionally it complicates skin malformations and benign tumors, notably dermoids and wens—*Medical Journal and Record*, April 20, 1927, cxxv, 8.

**Petit Mal or Cardiac Disturbance?**—G. A. Sutherland cites several cases illustrating the error in diagnosis that may result from failure to recognize that certain forms of cardiac disturbance may cause symptoms closely simulating those of petit mal. In attacks suggestive of petit mal there may be present at times a condition of tachycardia, with pulse rate of over 160 per minute, without other obvious cardiac changes. Such attacks may be characterized by loss of consciousness, screaming, giddiness, falling down, and sensations of pain in the chest or abdomen. The attack is usually sudden in origin, brief in duration, and sudden in cessation. The symptoms of an attack are present only during the period of paroxysmal tachycardia, and usually accompany the onset of a new cardiac rhythm. An attack is often definitely induced by excitement, nervous shock, or exertion (running, etc.). While an organic basis of disease of the heart may be present, a similar condition of paroxysmal tachycardia with symptoms may occur in children with organically sound hearts. When the symptoms above outlined are manifested before the child can describe sensation they may easily lead to a mistaken diagnosis, especially if the doctor does not see the patient during an attack, and does not examine the heart at the same time—*British Journal of Children's Diseases*, January-March, 1927, xiv.

# LEGAL

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York.

## THE HOUSE OF DELEGATES OF THE AMA TAKES ITS STAND AGAINST THE ENACTMENT OF RESTRICTIVE LAWS REGULATING THE DOCTOR'S RIGHT TO PRESCRIBE SUCH THERAPEUTIC AGENTS AS HE MAY DEEM NECESSARY

At the meeting of the House of Delegates of the Medical Society of the State of New York held in Niagara Falls on the 9th day of May, 1927, the following resolution introduced by Dr T C Chalmers was adopted

"RESOLVED; That the House of Delegates of the Medical Society of the State of New York at its annual meeting at Niagara Falls on May 9, 1927, and representing, as it does, more than ten thousand duly licensed physicians of this state, mindful, as it is, of the solemn duty of the doctor to render to his patient whatever treatment the true teachings of science declare to be necessary or beneficial in caring for the sick, and resenting with stern disapproval any arbitrary and unscientific curtailment of this obligation, realizing full well that to prevent the physician by arbitrary regulation from using for his patients' benefit whatever therapeutic agent his scientific knowledge and his conscience dictate, emphasizing its disassociation with any political issue, commonly referred to as "wet" or "dry" in unmeasured terms condemns this unjust, unwise, unsound, arbitrary and unscientific curtailment of and reflection on the medical profession as a whole, and therefore, not in its own behalf but in that of the lay public, whom it seeks to serve, earnestly petitions for the immediate repeal of this section of the Volstead Law, and, be it further

"RESOLVED, That the delegates from New York State to the House of Delegates of the American Medical Association be instructed to present and by all proper means to advocate the adoption of a memorial to the Congress of the United States, demanding the immediate repeal of that section of the Volstead Law and to employ all legitimate and honorable means for the education of the American public on this vital question "

At the meeting of the House of Delegates of the A M A held at Washington on May 18th, the resolution of the New York State Medical Society was referred to the Reference Committee on Reports of Board of Trustees and Secretary. The report of this Reference Committee was

adopted. In that report, among other things, we read

"The condition of hysteria into which the country was thrown by the struggle over the prohibition amendment has apparently subsided and the time has come when the American Medical Association should state plainly its attitude with regard to the use of alcohol and alcoholic liquors as therapeutic agents, as well as the position in which the physicians of the country are placed by the present unfortunate state of affairs. Such a statement should have no political bearing whatsoever and is intended to deal with the matter only from the practical and scientific medical standpoint. Alcohol is often very helpful in the treatment of disease and is being used in the practice of a very large number of doctors, many of whom believe it to be an essential and life-saving remedy. These doctors are confronted by a most deplorable situation brought about by the framers of the Volstead Act who unintentionally, we believe, limited the amount of alcohol for one patient to a pint in ten days. Such physicians believe that in certain cases of serious illness a pint in ten days would be useless, and that law-abiding physicians have no other alternative than to violate the law in order to save life. This is wrong and should be corrected. We believe it will be promptly corrected if the situation is properly presented to the authorities in charge."

Further in its report which was adopted, the Reference Committee recommended the adoption of the following resolution

"RESOLVED, That the American Medical Association declares its adherence to the principle that legislative bodies composed of laymen should not enact restrictive laws regulating the administration of any therapeutic agent by physicians legally qualified to practice medicine."

And further the report advised a referendum to be sent to all of the duly licensed physicians of the country, which should seek answers to the following questions

"(a) Do you believe that legislative bodies should enact laws regulating or limiting the prescribing of therapeutic agents by legally qualified physicians?"

"(b) Do you believe that alcohol and alcoholic liquors as listed in the latest edition of the United States Pharmacopeia are useful therapeutic agents in the treatment of disease?"

And finally this resolution was recommended and adopted

"RESOLVED, That the trustees of the American Medical Association be requested to send to every registered physician practicing in the United States a ballot requesting him to vote on the following question

"Are alcohol and alcoholic liquors as listed in the latest edition of the United States Pharmacopeia, useful therapeutic agents in the treatment of disease?"

And be it further

"RESOLVED, That the trustees of the American Medical Association be requested to submit the returns of this questionnaire in a memorial to Congress, asking that the restrictions on the quantity of alcohol and alcoholic liquors that may be prescribed for the sick be removed"

Stimulated, no doubt, by the stirring resolution which Dr Chalmers carried through the House of Delegates of the New York State Medical Society, the A. M. A. has thus come forward boldly and bravely in defense of the qualified doctor's right to prescribe whatever in his judgment is best for his patient. This great representative body of physicians of America thus strikes a blow in the cause of liberty itself.

If Congress has the right to say how much alcohol a physician may prescribe, it would have an equal right to tell the doctor what amount of insulin should be used for diabetes, or when, under what circumstances or in what amount any other drug or therapeutic agent might be employed for the alleviation or the cure of disease. The assertion of such a right is tantamount to a return to the Dark Ages. It is a negation and a repudiation of all of the teachings of science, and is a declaration that laymen are more competent to prescribe and advise for human sickness than are those who have spent their lives in this scientific study and who have been authorized by the State itself to carry on the work for which,

through years of study, experience and hard training, they have become equipped.

This subject wisely has been taken out of the controversial political domain involved in the so-called wet and dry issue. Doctors as such have no interest in either side of that bitter and unending dispute. They are taking no position either for or against the "Wets" or the "Drys." All that they say is that in certain cases one pint of alcohol in ten days for a patient would be useless. Recognizing this, many doctors no doubt, confronted by a choice of evils, that is, the breaking of a law or the failure to save life, have deemed it necessary to select the former as the lesser of the two. This is a deplorable situation. It should be changed. And now the doctors are doing all within their power to bring about a change. They deserve, they should receive and they have received the commendation of every fair-minded and intelligent citizen of the United States.

Warmly commending the action of the American Medical Association, the *New York World* in an editorial declared

"There is no question where responsibility for this situation lies. It lies in the hands of Congress. The Supreme Court has upheld the right of Congress to limit the use of alcohol by the medical profession. But there is no act of God or man requiring Congress to believe that it knows more about the problems of the medical profession than the medical profession knows itself. And if the medical profession appeals to Congress, when it meets again, to revoke its fiat, the appeal is likely to receive a more reasonable answer than it would have received five years ago. For we are getting away from the notion that the Volstead Act is perfect, that sickness as well as morals can be put in nice categories by law, and that Congressmen are all-wise as physicians."

No intelligent person with an open mind, regardless of his approval or disapproval of the Eighteenth Amendment and the Volstead Act, can fail to commend and endorse this action of the great national body of physicians of America. Let us hope that this intelligent, scientific, strong and patriotic move will force our Congress to eliminate from its laws all statutory attempts to curtail science and to prevent the physician from rendering to his patient all the service, care, attention and therapeutic agents which, in his judgment based upon his scientific knowledge, study and experience, he may deem necessary.

### CLAIMED ARSENIC POISONING

A physician, while in attendance at the clinic of a hospital, saw a patient who complained of pains in the hands and forearms, with numbness in the hands, and that the

condition had existed for about two months. She also gave a history of having had much domestic worry for the past several years, was extremely nervous, had slept poorly and

had bad dreams. She had also suffered from a slight indigestion and noticed that her eyelids had been slightly swollen.

Upon examination, the physician found that her eye grounds showed slight fuzziness of the lower edges of both discs. Her heart showed a pre-systolic murmur at the apex and thrill accentuated second pulmonic sound. Examination of the lungs showed crepitant rales at both bases and right axillary region. Her tonsils were hypertrophied and cryptic. A diagnosis was made of neurosis. For her muscular pains a rheumatic mixture was prescribed which, on her second visit to the clinic, she complained had made her sick to her stomach, although the pains were less. In substitution for the rheumatic mixture she was given five grams of sodium salicylate four times a day with three-quarters of a grain of luminal twice a day.

On her third visit to the clinic she was advised to have an X-ray of her teeth and given a general tonic for her nervous condition.

When next seen, she stated that her arms had been better for several days. The X-ray of the teeth showed an abscess of the second upper left bicuspid, and she was advised to have the abscessed tooth removed.

She returned about two weeks later with a rash on her forearms and left arm above the elbow which was confluent and itched. A rash was also present over the back of both legs below the knees and particularly extensive about the ankles. For the relief of this condition she was given calomine lotion and a digestive mixture of rhubarb and soda with cascara, and was also advised to take one-half ounce epsom salts on the following morning.

This was the last time that the patient visited the clinic.

Nothing further was heard from this patient by the physician until about a month later when he received a telephone call and a man inquired as to the treatment that the patient had received.

About a month thereafter, a person called on him at his office, stating that he was a justice of the peace and that the patient for the past month or more had been ill in a hospital in New Jersey and that the doctors treating her had diagnosed her condition as arsenic poisoning. The person calling upon the doctor endeavored to procure a settlement from him. The doctor, not acceding to the demands of his caller, was subsequently made a party defendant in an action of alleged malpractice. In this action it was alleged generally that the defendant physician in his treatment of the plaintiff was negligent and careless and had improperly prescribed for her, and that by reason thereof she was rendered sick and disabled and confined to her bed and home for about nine months.

It was also charged by the plaintiff that the defendant was negligent in having prescribed a drug containing too much arsenic and that the plaintiff suffered from arsenic poisoning, requiring treatment for about three months.

The plaintiff, not making any serious attempt to bring this action on for trial, in due course a motion was made on behalf of defendant doctor to dismiss the same for lack of prosecution, and upon the return of the motion an order was granted dismissing the complaint.

---

### RETAINED PLACENTA—VAGINAL FISTULA

An action was instituted against a physician and a mid-wife.

The complaint charged that on the 9th of July, the plaintiff, being pregnant and about to give birth, engaged the defendants, who represented themselves to be a skillful physician and a skillful midwife, to deliver her of her child.

It was charged that they both negligently and unskillfully conducted themselves, causing the patient to be lacerated and torn and also causing the death of the patient's child, that by reason of the acts of the defendants the patient was permanently and seriously injured and her physical, mental and nervous system impaired, and she sought in this action to be compensated for these injuries.

About 6 o'clock on the morning of July 11th, the defendant physician was called by the

plaintiff's husband. Upon arriving at the patient's home he found a midwife in attendance upon the patient and several other women present. The midwife stated that the patient was not having any labor pains. The physician found the patient in bed with the head of the foetus delivered and the remaining parts in the vaginal canal and uterus. The physician told those present that the child was dead. Upon examination of the patient he found her pulse and heart fair. She had a temperature of about 100°. The patient stated that she had been having pains for the past two or three days, but the pains had gradually grown weaker, and also stated that she had not felt life for about two weeks.

The physician observed the patient for some time and saw that the pains came irregularly

and from two to ten minutes apart and were very light

The patient not making any progress, another physician was called in consultation. An anaesthesia was administered to the patient and the child delivered by a low forceps extraction. The physician found the foetus full sized, pale, jaundiced and lifeless and, judging from its appearance and odor, he was of the opinion that the foetus had been dead at least two weeks. The cord was tied and cut and the patient left in bed resting quietly. An attempt to deliver the placenta was not successful.

The defendant left the patient about 9 A. M. in the care of the other physician. He returned at about 10 15 A. M. and found that the placenta had not as yet been delivered. He ordered whiskey and water as a stimulant and no other medication. He returned again at about 5 30 P. M. and found the patient in the same condition, resting quietly. The placenta had not been delivered and there was no bleeding. The patient's pulse was a little rapid and she complained of some pain in the lower abdomen. At this time the defendant physician advised the husband that if the placenta was not delivered before the following morning he would call to his assistance another physician to aid in the delivery of the placenta.

On July 12th, at about 8 A. M., the physician called on the patient and upon examination found her in very poor condition. He explained to the patient's husband the condition of the patient and requested that the patient be sent to the hospital, but the husband refused to send the patient to the hospital. At this time the patient's pulse was about 120 and the temperature 101 degrees. The defendant then procured the written consent of the patient's husband for the delivery of the placenta and, under a general anaesthesia administered by another physician, the placenta was delivered without difficulty, the patient being in a serious condition during all of this time. After the delivery of the placenta the uterus and vaginal canal were irrigated

with a weak iodine solution. The placenta, upon examination, was found not to be the usual healthy placenta, it was dry, putrid, grayish looking and slightly smaller than the normal placenta. There was no bleeding but there was a small serous discharge. Upon completion of the delivery of the placenta the patient was returned to bed and a stimulant of whiskey and water ordered for her, and also plenty of fluids.

The patient's temperature continued for about ten days, gradually diminishing to normal. During the next sixteen days the patient was seen ten times by the defendant physician. The lochia was a putrid, greenish-yellow discharge, and the physician ordered lysol douches externally.

During defendant's post-delivery attendance upon the patient she remained in a generally weakened condition. Strychnine and whiskey were ordered and plenty of fluid food. He also prescribed soap suds enemas when necessary. The patient was in bed all of this time.

About July 20th, the defendant physician informed the family that he would leave for his vacation about the first of August and would arrange for another physician to take his place. On the day of his last visit to the patient, July 27th, he was informed by the patient's family that they would get a doctor to attend the patient.

On August 14th the patient was removed to a hospital with a diagnosis of vaginal fistula. She was discharged from the hospital on August 21st. No diagnosis of a vaginal fistula was made by the defendant physician at any time.

The uterus was contracting but had not completely resolved when the patient was last seen by the defendant physician, on July 27th, and the uterus could be palpated above the brim of the pubic arch when the defendant last saw the patient.

When this case came on for trial the plaintiff failed to sustain her complaint against the defendant physician and at the close of the plaintiff's case the action was dismissed as against him.

# NEWS NOTES

## THE TRI-STATE CONFERENCE

The sixth Tri-State Conference of the officers of the Medical Societies of New York, New Jersey and Pennsylvania was held in the Hotel Casey, Scranton, Pa., on Saturday, June 18, 1927, with the following officers present

From New York, Dr J E Sadlier, President, Dr H R. Trrek, President-elect, Dr J S Lawrence, Executive Officer, and Dr Frank Overton, Executive Editor

From New Jersey, Dr Walt P Conaway, President, Dr J B Morrison, Secretary, and Dr H O Reik, Editor

From Pennsylvania, Dr H W Albertson, President, Dr A C Morgan, President-elect, Dr Frank C Hammond, Editor, Dr Walter F Donaldson, Secretary, and Dr L G Redding, President of the Lackawanna County Medical Society. These were the guests of the Medical Society of the State of Pennsylvania at a noon luncheon

The Tri-State Conference was designed to afford the officers of the three State Societies the opportunity to discuss the problems which are common to the medical profession of the three states. Concerning the value of the conference, Dr Fisher in his annual report said

"About two years ago, representatives of the Medical Societies of New Jersey and Pennsylvania approached us with the suggestion of holding a conference between the officers of the three Societies, for the purpose of discussing certain medical questions that involved the three states, with the idea, of probably suggesting uniform legislation

"The first meeting was held in Atlantic City a year ago last November. Since then there have been four conferences, one in Philadelphia, one in Atlantic City and two in New York, at which such subjects as, 'The Nurse Question,' 'Workmen's Compensation,' 'Anti-Quack Legislation' and 'Relations of the Medical Organization to Voluntary Public Health Agencies'—have been discussed with great profit to all. We are learning that some of the problems that give us the greatest concern in this state, are common to the three states, and, in some instances, they have given us suggestions with regard to their solution, while to the solution of others we have been able to contribute from our experience

"These conferences should be continued, in my opinion, not only because of the advantages which arise from a discussion of common problems, but for the sake of developing

a closer fraternal spirit with these two powerful neighboring Societies" (page 455 JOURNAL of May 1)

The House of Delegates endorsed the recommendations of Dr Fisher, (See Sec. 52 of the minutes, JOURNAL of June 15, 1927, page 680)

The conferences have been of increasing value as those attending them have become better acquainted with one another and with the problems in the three states. The fourth conference, held in Atlantic City on December 4, 1926, was noted for its informal discussion of problems of great practical value (see this JOURNAL December 15, 1926, page 1049)

The fifth conference, held in New York City on February 26, was devoted principally to a more formal discussion of problems which are being handled by the State Society of New York (see this JOURNAL, March 15, 1927, page 316)

The Scranton conference was even more practical than the others, for it was based on the foundation of understandings and acquaintances that had been formed in the preceding conferences. Two subjects were discussed, 1 Educating the Public in Medical Matters, and 2 The statewide anti-diphtheria campaign

The subject of the medical education of the public was presented by Dr Frank C. Hammond, of Philadelphia, editor of the *Atlantic Medical Journal*, the official organ of the Medical Society of the States of Pennsylvania and Delaware. Dr Hammond reviewed the field of public education in medicine and quoted at length from the addresses of the last President of the American Medical Association, Dr Wendell C Phillips, who had continually emphasized lay medical education throughout his year of office. Dr Hammond ascribed to the Illinois Medical Society the leadership among the states in promoting the education of the people and said that \$286 of the annual dues of each member were devoted to this work. The State Society had listed a large number of physicians who were willing to give popular lectures to organizations such as parent teachers association, Rotary clubs and high schools. Newspaper articles were widely used, radio talks were given, movies on health topics were shown, and an extensive campaign of instruction was conducted along every standard line in which the people could profit by medical instruction

The State of Texas was also quoted as doing advanced work in lay medical education, especially by the extensive use of paid advertisements in the newspapers. Dr Hammond quoted from an Illinois report regarding the reactionary atti-

tude of unorganized doctors (non members of county societies) toward civic problems, and the very great contributions of organized medicine to citizenship

Dr Sadlier reported for New York State that popular medical education had been done extensively by the State Department of Health and voluntary health organizations, especially the State Charities Aid Association. The State Medical Society was now entering the field actively in an advisory and directive capacity and was securing harmony and avoiding duplication of efforts by the functioning of a committee on public relations. The next step would be to secure the appointment of a committee on public relations in every county medical society, in order that the physicians might assume the leadership in all medical matters in their respective counties.

Dr Sadlier quoted the experience of the New York State physicians with periodic examinations to illustrate the need of the education of the people in health topics. While talks and lectures have been given urging persons to go to their family physicians on their birthday and secure an examination and a survey of their physical condition, yet the people are so far from accepting the advice that doctors feel it to be presumptuous on their part if they solicit the examinations.

Dr Sadlier also said that the older doctors were making the examinations to a much greater extent than the more recent graduates. This fact is surprising, for one would expect the young doctors to be fully informed regarding the newer developments of medicine. Dr Sadlier said that the New York State Medical Society was planning to invite the Deans of the Medical Schools to a conference to consider the education of the students in the subject of organized medicine, and that periodic examinations would be an important subject for discussion.

Dr Morgan said that he had addressed a medical meeting at which sixteen pre-medical students from a local college were present, and he talked on the subject "How to Run a County Medical Society." He believed that such lectures should be given to all medical students.

Dr Morgan also said that the Philadelphia County Medical Society had admitted Junior Members consisting principally of hospital internes (The Kings County, of Brooklyn, has provision for a similar membership).

Dr Hammond called attention to the course of six lectures given in the Washington University School of Medicine, St. Louis, which was described on page 1751 of the May 28th issue of the *Journal of the American Medical Association*. While these dwelt largely on the ethical relations of physicians to one another, they could be expanded to include their duties to the medical societies and to the public.

Dr Overton contrasted the attitudes of the people toward periodical examinations with that

toward diphtheria prevention in which an intensive campaign of public education had been conducted. The result has been that the children flock to the clinics where the immunizations are given, and parents are bringing increasing numbers of children to their family doctors for the injections. Periodic examinations will become popular when the people become educated as to their value.

Dr Conaway said that New Jersey had taken up the problem of the health education of the public a year ago, and that Dr Reik, the Executive Secretary had spent about half of his time going about the state in order to lecture to county societies and lay organizations on public health topics. The work was so important and promising that the State Society had made a special appropriation of \$4,000 for public health education. New Jersey plans to abandon the plan of a lobbyist in the State Capitol and to conduct the legislative campaign by means of education. The State Society expects much help from the Women's Auxiliary in the educational work, and will use the film on periodic examinations. Dr Conaway urged the doctors to assume the leadership in public education as in other health matters, for it is one of the most important of the newer activities of the medical societies.

Dr Reik brought up the subject of the need of censorship, supervision and criticism of radio talks on health subjects and said that the Radio Corporation of America had an advisory board representing various professions which reviewed the matter that was broadcasted. On motion of Dr Morgan the resolution was passed suggesting that a physician be put on the advisory board.

Dr Morrison said that the greatest activity of a State Medical Society is the education of its own members, especially in their civic duties. A year's presidency of a Kiwanis Club gives a man a civic outlook that is broader than that supplied by fifteen years of the office practice of medicine.

Dr Albertson said that the majority of County Medical Societies in Pennsylvania published monthly bulletins, and that they often contained articles for educating the people. He also discussed the kind of articles which both the newspapers and their readers demanded. He condemned the ordinary health columns in which the correspondents gave symptoms on the basis of which the editor was expected to make a diagnosis and to advise treatments. Medical Societies could not stand for that sort of so-called medical education.

Dr Albertson said that in his inaugural address last fall he had proposed that the State Society take up the activity of the education of the public in health matters and that a plan would probably be adopted at the annual meeting in Pittsburgh early in next October. He said that his State Society had taken up the plan of advocating a periodic examination of every person on May day, but that many doctors had objected

to it because some public health nurses had urged some people to go to clinics for the examination. There is great need that the educational programs be started with the doctors. Pennsylvania needs a fulltime field secretary in order to conduct the work of educating both the doctors and the people.

Dr Hammond described the plan of the Philadelphia County Medical Society in publishing medical articles in a Philadelphia newspaper under the name and authority of the Society. He also said that health articles were broadcasted with the names of the authors, and then the names were omitted when some physicians made objection on the ground of advertising, but later the names of the authors were again announced, for it was the policy of the radio managers to give full publicity to the authors of whatever was broadcasted.

The second major topic that was discussed in the Tri-State Conference was the state-wide anti-diphtheria campaign. Dr J S Lawrence gave a description of the work in New York State and showed how it depended on two principal factors, 1. The support of physicians, and 2, the education of the people. Dr Lawrence said that his talk would be a demonstration of medical publicity and education as applied to one concrete disease. He described the two principal methods of securing the immunization of the children by means of injections of antitoxin, 1, by means of public clinics, especially in the schools, and 2, by ordinary office calls on private physicians.

Dr Lawrence first described the development of the plan of campaign by a committee representing the State Medical Society, the State Department of Health, and the leading voluntary organizations. The plan included the endorsement of the County Medical Societies, articles in newspapers, posters on bill boards, and in doctors' offices, slides in moving picture houses, and many other devices used in public health campaigns.

Dr Lawrence described the work in the two cities of Newburgh and Schenectady in order to illustrate the two principal methods of dealing with the children to be immunized. Newburgh adopted the methods of an intensive campaign conducted by all the available organizations headed by the Newburgh Bay Medical Society and including public health nursing societies, parent teachers associations, civic clubs, churches, newspapers and a long list of other organizations. The actual immunizations were given in clinics conducted by the physicians, with the help of the civic organizations for the transporting and care of the children. The campaign was a great success, and the expectation is that as a result the people will go voluntarily to their family doctors to have their children immunized in the future.

Schenectady had adopted the plan that no public clinics should be held, but that the physicians should hold themselves ready to give the immuni-

zations to the children that were brought to their offices. The Schenectady County Medical Society sponsored the plans which were adopted and included the appointment of a work-committee, the employment of a paid secretary, the distribution of literature, a house to house canvass, the cooperation of public health nurses and provisions for recording and summarizing the number of immunizations given. The results have been slow as compared with those in Newburgh, but nevertheless they have been valuable and will probably be permanent for they do not depend on free clinics.

Dr Walter F Donaldson described the methods followed in some of the counties of Pennsylvania that in Cambria County being the most striking. The county has a population of 217,000 and has a mining population that includes the City of Johnstown. The plan of work was that the Red Cross assumed the leadership. Its representatives secured the consent of the parents and brought the children to central clinics which the doctors attended in alphabetical relation, each receiving \$25—for a day's work. The work was a great success, 17,000 children being immunized within the year.

Dr Donaldson described the different plans that were adopted in some other counties with varying degrees of success depending largely on the cooperation of the physicians.

Dr Morrison said that New Jersey was now planning to start the immunizations on a state-wide basis, but the State Medical Society had declined to assume the leadership on account of the cry of "Medical Trust." However, the State Society had asked the State Board of Health to assume the leadership and had promised to support the movement. The plans include the cooperation of the State Tuberculosis Committee and other voluntary health organizations.

Dr Morrison spoke in favor of the plan that the physicians should assume the leadership in the anti-diphtheria campaign, and said that the doctors who would not cooperate in the campaign were forcing the issue of State Medicine, for other organizations would assume the leadership and would do the work under the very plan of State Medicine that the doctors wished to avoid.

Dr Hammond said that there was need of educating the doctors of Philadelphia, for many physicians were indifferent simply from ignorance. The City Board of Health had promoted the immunizations, but much educative work would have to be done among the doctors.

Dr Leonard Redding brought up the objections which many doctors have to giving their services to clinics free. Many physicians had said that the doctor should not be expected to give his services free any more than that the grocer should give away sugar.

Dr Sadler said that this objection would have to be met by the education of the doctors in their

civic duties. If there was a great work in medical civics to be done, the doctors should rise to the opportunity and do it. He quoted the example of an elderly health officer who had immunized several hundred children without expecting pay, because all he wanted to do was to suppress diphtheria. In the adjourning district nothing was done while the doctors were waiting for pay.

Dr Morrison said that ten years from now the doctors will be receiving their pay in thousands of dollars for immunizations which the doctors were now doing without primary regard to the financial returns. The doctors need to have a broad outlook beyond the immediate present.

Dr Albertson said that if State Medicine comes it will be because some doctors are willing to accept a few dollars for paltry work. The great

need was that the officers of the societies should go back to their constituents and give them some of their enthusiasm and outlook into the future.

Dr Trick said that if the public will contribute the organization and the money, the doctors should be willing to make their own peculiar contribution of professional skill, at least as a demonstration of the value of a public health procedure. The selfishness of individuals should not stand in the way of the medical profession doing civic work.

The entire conference was characterized by the profuseness and practicality of the ideas that were presented. Every doctor present gained new ideas and inspiration as he saw how the different counties and states had evolved their solutions of problems that were common to all.

## DISTRICT BRANCH CONFERENCES

*The coming annual meetings of the District Branches have been planned in a series of conferences of the officers of the State Society with those of the District Branches and their component county societies after the precedent that proved successful last year. The following is a record of the conference held in each of the eight District Branches.*

### FIRST DISTRICT BRANCH

At the invitation of Dr. Cunniffe, President of the First District Branch, the following responded to a meeting of the Executive Committee which was held at the Cornell Club, New York City, on Tuesday evening, June 7, 1927.

Dr. Cunniffe, President, Dr. Kline, 2nd Vice-President, Dr. Clock, Secretary, Dr. Howell, Treasurer, Dr. Titus, President of Westchester County Society, Dr. Friedman, President of Bronx County Society, Drs. Sadlier, Farmer, Dougherty and Lawrence. Dr. Patterson, President of New York County Society, was unable to attend, but requested that Dr. Dougherty, the Secretary, represent him.

It was decided that the next annual meeting of the District Branch should be held in the Bronx on Thursday, October 20th. Suggestions for the program included short papers on preventive medicine, post-graduate education and periodic examination, and two or three scientific papers to be read by men prominent in their particular fields. In this connection the following were suggested: Dr. Judd, Drs. Minot and Murphy, and Dr. Healy.

That the attendance at the First District Branch meeting has never been as large as it was thought it should be, was attributed in part to the meager announcement, and it was decided that this year at least three notifications should be sent to each member in the District concerning the time, place and program. It was also sug-

gested that in the first announcement each member be notified that by virtue of being a member of the County Society, he is a member of the District Branch and is, therefore, expected to attend the meeting if possible. It was brought out that in the past some men have expressed surprise when told that there was a District Branch Society and that they were members of it.

Dr. Sadlier urged the officers to realize that they have an opportunity of developing in their district a large and important meeting. He called attention to the discussion that was had in the afternoon with members of the Second District Branch, where he made the same suggestion. He thought that because of the large membership of these two District Branches and the compactness of their territory, their annual meetings should rival the State Society meetings in attendance and importance.

Dr. Farmer outlined the program of his Committee and invited the officers of the County Societies to call upon him for assistance in developing courses of post-graduate education. He stated, however, that he is thoroughly familiar with the splendid work that New York and Bronx counties have been doing, and supposed they mean to continue it, but he thought that probably his Committee could be of service in the other counties. He called attention to the important Committee on Public Health that every County Society should have and urged that if

any of the counties represented does not have such committee, that it create one of the earliest opportunity, and he outlined to some extent the work and importance of such committee

Dr Friedman briefly outlined the splendid work that is being done by the Bronx County Society, especially in the field of periodic examinations. He described the pamphlet that his Society has prepared in collaboration with the New York Tuberculosis Association and which is being distributed by the members of the County Societies to their patients.

Dr Howell stated that Orange county has a very active Public Health Committee. Dr Kline spoke in praise of the excellent work that was done in Rockland county through the post-grad-

uate lectures on obstetrics and pediatrics. He also commented upon the diphtheria immunization activities, but deplored that most of it is being done by health officers instead of practicing physicians.

Dr Dougherty told of how periodic examination activities were started in New York county, how Dr Wightman prepared the film which is widely known by this time, and also of the pamphlets that were prepared in collaboration with the Tuberculosis Association and distributed by them to the lists of patients submitted by physicians.

Dr Cunniffe stated that he would immediately give to the press an announcement concerning the annual meeting.

---

## SECOND DISTRICT BRANCH

The Executive Committee of the Second District Branch was called in conference by the President, Dr Turrell, on Tuesday, June 7, 1927, at the Shinnecock Hills Golf Club, Southampton, where the Associated Physicians of Long Island was in session. Those present were Dr Turrell, President, Dr Thomas, President of Queens County Society, Dr Overton, President of Suffolk County Society, Dr Sadler, Dr Farmer, Dr W H Ross, Dr VanCott and Dr Lawrence.

The date and place of the next annual meeting of the Branch were discussed at length, and it was decided tentatively that the meeting should be held in Jamaica in a hall near the railroad station, and on some date in October.

In discussing the program it was decided to repeat that portion of the program of last year which dealt with a review of the activities of the component County Societies, because it was agreed that this was a very successful feature. In order to evaluate more properly the activities of the counties, it was suggested that persons

well informed in anti-tuberculosis work, as, for instance, Dr Rathbun of Chautauqua county, and a representative from Cattaraugus county and another from Syracuse, be invited to tell, at the same time, of the anti-tuberculosis activities in their communities.

It was also agreed to invite two or three leading scientists to read papers. Much consideration was given to the discussion of plans that would increase the attendance at the annual meeting. It was deplored that, regardless of the excellent program last year, the attendance was very small. It was thought that the drawback in the past has been that the meeting and its program were not sufficiently advertised and it was, therefore, agreed that for this year the program should be completed as early as possible and that several notices should be sent to every physician in the District beginning probably three weeks in advance of the date of the meeting. The desirability of sending invitations to physicians outside of the District, in counties neighboring the Second District, was favorably considered.

---

## THIRD DISTRICT BRANCH

The Executive Committee of the Third District Branch met in the University Club, Albany, at 1:00 P M, Wednesday, June 1st, at the call of Dr Edgar Vander Veer, the President. The following were present in addition to Dr Vander Veer: Dr Rossman, 2nd Vice-President, Dr Rapp, Secretary, Dr Billings, Treasurer, Dr Odell, 1st Vice-President, Dr Mambert, President of Columbia County Society, Dr Cox, President of Albany County Society, Dr Hambrook, President of Rensselaer County Society, Drs Farmer and Lawrence.

It was decided to hold the next annual meeting on Saturday, October 1st, and Dr Hambrook's invitation to have the meeting in Troy was accepted. Dr Hambrook explained that they have a new hotel—the Hendrick Hudson—which could very readily accommodate any number that might choose to come. It was decided that the program should consist of a series of clinics on important subjects, given at the several hospitals in Troy in the forenoon, followed by a luncheon at the Hendrick Hudson and, subsequent to that, a series of scientific papers.

No readers of scientific papers were decided upon at the meeting. Dr Hambrook suggested that there are several men in Troy who have done work of outstanding character, and he was quite certain that he could get some of those to take part in the program. He also suggested that, in anticipation of the acceptance of his invitation, he had already considered the appointment of a committee on arrangements.

Dr Farmer urged the members to avail themselves of the opportunity for post-graduate work, and discussed with members the reasons advanced for the lack of success in some of the courses that were attempted in this district a year ago. There was some preference expressed for a course of lectures on cancer.

Matters of local interest were then brought up for discussion. Among them was a report that the enforcement of the law which requires examination of the eyes of applicants for motor licenses is being left to state troopers and not to physicians. It was suggested that the executive officer make inquiry from the proper authorities as to the prevalence of this practice.

Dr Rapp reported that in Greene County the State Department of Health has, for some time, been endeavoring to conduct well baby clinics, but that he, as health officer of one community—and physicians generally—have objected to this activity on the part of the Department on the ground that it is not needed, that the physicians are giving the children all necessary attention, but that the agent of the Department of Health has been so insistent recently that, without the consent of the physicians, Dr Rapp understands he has arranged for such clinics and, so far as Dr Rapp knows, no physician has accepted an invitation to assist at the clinics. This being a matter of public health, Dr Farmer said that he would be glad to be kept in touch with the situation and that, if advisable, he would discuss the matter with Commissioner Nicoll.

Before adjournment, it was suggested that inasmuch as there seemed to be other matters of interest in the district that should be discussed, President Vander Veer probably would call another meeting of the committee before the annual meeting.

#### FOURTH DISTRICT BRANCH

At the request of Dr Barton, President of the Fourth District Branch, the following met in executive committee at the Queensbury Hotel, Glens Falls, on Thursday, June 9, 1927. Dr Barton, President, Dr Munson, 1st Vice-President, Dr Comstock, Secretary, Dr Reynolds, President of St. Lawrence County Society, Dr Fox, President of Montgomery County Society, Dr Prescott, President of Washington County Society, Dr Birdsall, President of Warren County Society, Drs Farmer and Lawrence. Dr King, President of Saratoga County Society, wired that he was sick in bed, hence it would be impossible for him to attend the conference.

In discussing the time and place of the next annual meeting there was general approval expressed at the plan adopted last year of having the meeting begin at noon of one day and extend to noon of the next day, because it gave an opportunity to those men who were obliged to come a long distance—and there are many such in this district—to arrive at the opening of the meeting by leaving their homes early on that same day and, likewise, give them an opportunity to reach home the next day and, yet, stay for the end of the session.

Dr Barton stated that he had had an invitation from Dr Stanton to hold the meeting in Schenectady this year. That proposal was received with approval by all present and it was recommended that Dr Barton or the Secretary, Dr Comstock, immediately get in touch with Dr Woodall, President of the Schenectady County Society, and have the invitation extended formally by that So-

ciety. The date selected is October 11th and 12th, the meeting to begin at noon on the 11th and close at noon on the 12th. Suggestions for the program included a series of clinics at the several hospitals and the General Electric Company on Tuesday afternoon, with a banquet and some entertainment in the evening, and on Wednesday morning a program of scientific papers, at which Dr Wilson, orthopedist of Boston, and representatives of the X-Ray Department of the General Electric, would be invited to read papers.

Dr Farmer spoke in appreciation of the extensive post-graduate work that has already been done in this district and expressed the hope that there would be much more in the future. He discussed at length with Dr Reynolds the courses of lectures that have been given in St. Lawrence county and the valuable points they have learned through their experience.

It was agreed that short papers on post-graduate courses, periodic examination and any other activity peculiar to the district, should be included in the program.

When it was agreed that the annual meeting this year should be held in Schenectady, there was also expressed unanimous approval of accepting an informal invitation extended by Dr Reynolds, to consider holding the annual meeting of 1928 in St. Lawrence county. And if such invitation is formally extended, it was agreed that the meeting should be held just before or about the 15th of September, in order that there might be more certainty of having delightful weather.

### FIFTH DISTRICT BRANCH

The Executive Committee of the Fifth District Branch met in Hotel Syracuse on Thursday evening, June 2, 1927. The meeting began with a dinner. The following were present: Dr. Charles Post, President; Dr. Page E. Thornhill, 1st Vice-President; Dr. A. B. Santry, 2nd Vice-President; Dr. W. J. McNerney, Secretary; Dr. Finley, President of Madison County Society; Dr. Olin, President of Jefferson County Society; Dr. Evans, President of Oneida County Society; Drs. Farmer and Lawrence.

It was decided to hold the next annual meeting in Syracuse on Thursday, October 13th, and the Onondaga County Society will be the host. The character of program was discussed, and while only a few names were mentioned as prospective persons to be invited to read papers, a list of subjects that would be most interesting was prepared as follows:

Periodic health examinations  
Standards of pre-natal care.  
Dermatology  
Industrial medicine  
Kidney function

It was also agreed that at least two short papers—one on post-graduate education and another on public relations—should be prepared by local men.

There followed considerable discussion of the manner of conducting the courses in post-graduate instruction, in which Dr. Farmer took an active part with representatives of the counties where courses have been held.

There was also considerable discussion of the function of a Public Relations Committee, and the need for such committee was strongly emphasized by those present who are Presidents of County Societies.

---

### SIXTH DISTRICT BRANCH

At the call of President Fish, the following members of the Executive Committee and Presidents of component County Societies, met in Ithaca on Wednesday, May 25, 1927:

Dr. W. G. Fish, President; Dr. LaRue Colegrove, 1st Vice-President; Dr. H. B. Marvin, Secretary; Dr. L. P. Larkin, President of Tompkins County Society; Dr. A. A. Bailey, Secretary of Cortland County Society; Dr. B. A. Hall, President of Chenango County Society; Dr. W. J. Farrell, President of Broome County Society; Dr. T. J. Burke, President of Chemung County Society; Dr. W. A. Moulton, Secretary of Tioga County Society; Dr. McMahon, Broome County Society, representing the Endicott-Johnson Company; Drs. Booth and Howland from Chemung County Society; and Dr. Lawrence.

The meeting began with a luncheon at the Hotel Ithaca. It was unanimously decided that the next annual meeting of the Branch should be held on Tuesday, September 27th. After much consideration was had upon two invitations, extended by delegations from Broome and Chemung counties, it was finally decided to accept Broome County's invitation. Final preparation of the program was left to the President and the local committee on arrangements that may be appointed by Broome County, with the understanding that the meeting would probably be held in Johnson City, and that a portion of the program would be devoted to a study of the medical work of the Endicott-Johnson Shoe Company. In addition, it was suggested that Dr. Britt would be asked to assist in providing a man to read a paper and give a demonstration of periodic health examinations, and that the committee should endeavor to

secure at least two outstanding men in their particular lines, preferably medicine or surgery.

In discussing the matter of membership of the County Societies, Dr. Farrell, President of the Broome County Society, stated that they had increased the attendance at their society meetings very materially by appointing a committee on membership and dividing the total membership of the society between these men asking each member of the committee either to call in person upon members allocated to him, or call them upon the telephone on the day of, or the day before each meeting of the society. It was suggested—and the suggestion was accepted by Dr. Fish—that he should make a survey of the County Societies, investigating the methods they are pursuing for increasing their membership and also ascertaining about how many physicians in the district are not members of their respective County Societies, and report his findings at the annual meeting.

In discussing the matter of insurance it developed that there is some misunderstanding among the physicians as to the advantages to be derived from carrying insurance under our group plan. It would seem wise, in addition to the valuable articles appearing in the JOURNAL, to have someone thoroughly familiar with our plan of insurance present the matter before the various County Societies at some one of their regular meetings.

The organization of Committees on Public Relations was heartily approved, and the Presidents of the County Societies asked for detailed information as to what the duties of such committees should be. It was suggested that an outline of the duties might be prepared by the standing

Committee on Public Relations and later submitted to the various County Societies

Enthusiastic reports were received as to the progress of immunization against diphtheria

Dr Lawrence reported for Dr Farmer, who was unavoidably prevented from attending the

meeting, that he was eager that the various County Societies should avail themselves of the opportunity of having lectures on medical or surgical subjects and ask that they make a selection of subject and get in touch with Dr Farmer at their earliest convenience

### SEVENTH DISTRICT BRANCH

The Executive Committee and Presidents of the component County Societies of the Seventh District Branch met in Geneva on Tuesday evening, May 24, 1927, at the call of the President, Dr Lytle. There were present in addition to Dr Lytle Dr Collier, 1st Vice-President, Dr Armstrong, 2nd Vice-President, Dr Lichty, Secretary, Dr Wentworth, Treasurer, Dr Bates, President of Cayuga County Society, Dr Paciulli, President of Yates County Society, Dr Gregg, President of Ontario County Society, Dr Green, Secretary of Cayuga County Society, Dr Britt, chairman of the Committee on Medical Economics, and Dr Lawrence

After some discussion, it was decided that the next annual meeting of the District Branch should be held either in Geneva or Clifton Springs, and the final selection of the place was left to the President. September 29th was chosen as the tentative date. A number of prominent men were named to be invited to read papers, and the President and Secretary were authorized to communicate with these in the order they were selected, with the idea of having at least two such men from a distance for the program. At Dr Britt's suggestion it was also decided to have a man very widely known as a teacher in periodic health examination methods, read a paper and demonstrate

the manner of making such examination and recording them

In Dr Farmer's absence, Dr Lawrence called attention to the splendid work that is being done in post-graduate education, and urged that the County Societies avail themselves more freely of the offer made by the State Society through its committee. Some other points referring to the activities of the District were discussed. As to membership of the County Societies, it developed that the physicians practicing in these counties are practically all members of the County Societies. Few of the counties have Public Health Committees and practically none of these are active. Plans were discussed for increasing their activity and for the appointment of committees in the counties where they do not already exist. The function of a Public Relations Committee was discussed and all seemed immediately to appreciate the need of such committee and agreed that at the first opportunity they would urge its selection in their own Societies.

There was a very enthusiastic report of the progress of the diphtheria immunization work in the various counties, except from one district, in which there is no opposition on the part of any of the physicians, but inactivity seems to be due entirely to lack of leadership.

### EIGHTH DISTRICT BRANCH

At the call of the Vice-President, Dr Thomas J. Walsh—in the absence of President Cottis, who is in Europe—the Executive Committee of the Eighth District Branch and certain of the Presidents of the component County Societies, met in Buffalo on Thursday, May 26, 1927. The meeting began with a dinner at the University Alumni Club. The following persons were present: Dr Walsh, 1st Vice-President, Dr W. Warren Britt, Secretary and President of Erie County Society, Dr R. H. Wilcox, Assistant Secretary, Dr F. H. Van Orsdale, Treasurer, Dr Leighton, President of Niagara County Society, Dr Cooley, President of Allegany County Society, Dr DeCeu, Past-President of Erie County Society, Dr Trick, President-elect of the State Society, Dr Farmer and Dr Lawrence.

The first order of business being to decide upon

the time and place of the next annual meeting, it was unanimously decided to hold it on October 6th at Glen Ayr. If, however, it is found impossible to hold the meeting there, the second choice of the committee would be Warsaw, and third choice, Batavia. Suggestions for the program include an invitation to Dr Thayer, President-elect of the American Medical Association, Dr Heyd, to give a paper on "Draining of the Gall Bladder," and Dr Crampton to read a paper upon and demonstrate periodic health examinations. Dr Farmer urged that the County Societies arrange at their earliest convenience for post-graduate courses, and also desired that some reference be made to post-graduate education in the program of the annual meeting.

In discussing the membership of the County Societies, only three counties being represented,

it was found that Erie had been conducting some vigorous membership campaigns, but that there are still many men in Niagara and Allegany counties who do not hold membership in the County Societies. It also developed that many of the County Societies do not have Public Health Committees, and Dr Farmer urged that they immediately organize such committees. It was later decided that in some of the smaller counties the two committees of Public Health and Public Re-

lations might be combined, with the understanding, of course, that the functions of the two committees, while closely related, are not at all identical. There was some confusion and lack of information shown among those present with regard to the group insurance plan, reenforcing the observation made at the Sixth District Branch meeting of the need of somebody conversant with our scheme presenting the matter to the County Societies in person.

---

## LAKE KEUKA MEDICAL AND SURGICAL ASSOCIATION

The twenty-eighth annual meeting of the Lake Keuka Medical and Surgical Association will be held Thursday and Friday, July 14 and 15 at Keuka Hotel, on Lake Keuka, one of the Finger Lakes in central New York State.

The meeting will open promptly at 10 a m Thursday, July 14th in the big open dance pavilion at Keuka Hotel, and will continue until Friday afternoon July 15th. It is expected that between two and three hundred physicians from all over the state will be in attendance.

Dr A H Aaron of Buffalo is the President, Dr Albert M Crance, of Geneva, is Vice-President, and Dr John A Hatch of Penn Yan is Secretary and Treasurer.

Extensive plans are well under way by the officers and directors to make this meeting one of the most interesting in the history of the association. Besides the scientific program which

will be fully announced at a later date, the committee are arranging some splendid speed boat races to be held each day of the meeting. There will be several fifty-mile an hour boats on the lake this year to compete for the challenge cup offered by the Lake Keuka Medical and Surgical Association, as well as other challenge cups offered by the local Yacht Club.

The association is almost twenty-seven years old. It was organized on August 14, 1900 by the Steuben County Medical Society at its summer meeting which was held at Gibson Hotel on Lake Keuka. The idea spread to other counties and the Association now includes twenty-two counties in Central and Western New York.

JOHN A HATCH, M D,  
Secretary and Treasurer,  
Penn Yan, N Y

---

## SCHOHARIE COUNTY

The semi-annual meeting of the Schoharie County Medical Society was held in the Parrott House, Schoharie, N Y, on Tuesday, May 17, 1927.

Officers nominated for 1928. For President, M Bruce, Vice-President, C L Olendorf, Treasurer, L R Becker, Secretary, H L Odell, Censor, W T Rivenburgh.

The Committee on By-Laws gave a preliminary report.

C F Wharton and J F Duell made application for membership. Their application was favorably reported by the Comitia Minora and they were duly elected.

Dr R J Wharton, Pediatricist, of Johnson City, N Y, read a paper on "Some Practical Points for the General Practitioner in the Diagnosis and Treatment of Disease in Infancy and Childhood."

Dr Robert E Plunkett, Director of the Division of Tuberculosis of the New York State Department of Health, gave a talk on

"The Family Physician and Tuberculosis," in which he emphasized the necessity of early diagnosis, the five positive diagnostic points, the careful extended instruction for each patient and the frequent examination of each contact. Dr Huntington Williams, District State Health Officer, opened the discussion of Dr Plunkett's paper and his remarks were followed by an animated general discussion.

We were greatly honored by having present with us the President of the Medical Society of the state of New York, Dr James E Sadlier, who spoke very entertainingly on the activities of the State Society and expressed the hope of a closer relationship between the several health agencies of our State.

Dr Nelson Borst of Poughkeepsie, a native of this county, gave us an interesting talk.

Withal the meeting was the best attended, all but three members being present, and the most enthusiastic of any we have had for several years.

H L ODELL, Secretary

## QUEENS COUNTY MEDICAL SOCIETY

The regular meeting of the Medical Society of the County of Queens was held at the Jamaica Lodge, I O O F, No 247, 159-29 90th Avenue, on April 26th, 1927, President Joseph S Thomas in the chair

The minutes of the March meeting, as published in the *Bulletin*, were approved

The following nine candidates were elected to membership Guido Boccardi, M D, 3541 10th Street, Long Island City, Robert R Eckert, M D, 8902 Sutphin Boulevard, Jamaica, L I, Dana Fletcher Downing, M D, 132-02 97th Avenue, Richmond Hill, L I, John Halliday Gillespie, M D, 3256 82nd Street, Jackson Heights, L I, Otto T Hofmeister, M D, 113-18 Sutphin Boulevard, Jamaica, L I, Milton H Morris, M D, 1930 Broadway, Far Rockaway, L I, Gerald Edwin Pauley, M D, 218th St and Jamaica Avenue, Queens Village, L I, John A Renwick, M D, 1502 Mott Street, Far Rockaway, L I, David Rothstein, M D, 3756 74th Street, Jackson Heights, L I

Dr A G Whelan, Chairman, rendered a brief report of the work of the Membership Committee

The President announced the resignation of Dr W J Lavelle, as chairman of the Committee on Public Health, and the appointment of Dr James G Howard as his successor to the Chairmanship of that Committee He stressed the importance of the work of this Committee to the Society and to the public

Dr D E McMahon, Chairman, reported for the Legislative Committee that the Governor to his credit had vetoed the Osteopath and Optometrist bills

The President announced that no applications had been received for physicians to the Camps of the Boy Scouts during the summer and emphasized the opportunity and advantage to physicians who could render this service

The following scientific program was presented

Paper—The selection of gastric and duodenal ulcer cases for different types of treatment, lantern slide illustrations By Dudley Roberts, M D

Dr Roberts discussed the subject of peptic ulcer in general as a basis for certain comments on

the selection of cases for various plans of treatment He called attention to the fact that we knew little of the causation of ulcer except that the stomach and to a lesser degree the cap tended to digest itself when the blood supply of an area was cut off The role of infection was more suggested by the results following removal of infection above than by anything in the way of experimental proof Attention was directed to the various types of ulcer as shown by the roentgen study and the rule laid down that any ulcer of the stomach should show a comparatively quick response to medical treatment in the follow-up roentgen study An increase in the size of the ulcer or the area of induration after a month or six weeks of medical treatment was a definite indication of surgical treatment Failure to diminish in size in two or three months was to be looked upon as a definite indication that medical treatment would fail Symptoms could not be depended upon at any time as a criterion of cure as remission of symptoms over long periods was the rule in gastric as well as duodenal ulcers In general it was held that the less the area of induration the more likely was medical cure to succeed and vice versa The fact that rather large indurated ulcers healed spontaneously or under medical treatment was well established by successive roentgen series

The statement was made that the bed treatment of ulcer was largely for the purpose of controlling the patient who otherwise would not adhere to a frequent feeding and alkali routine Surgery was frequently to be resorted to because of the difficulty of carrying out adequate medical treatment over a long period

Paper—Symptoms and treatment of perforated duodenal ulcer, with review of cases By Denis E McMahon, M D

Discussion by Drs C B Story, W J Lavelle, D E McMahon, A L Voltz, W H Barber, I S Startz, J S Thomas

Closed by Dr Roberts and Dr McMahon

Dr John H Barry addressed the meeting on the St John's Hospital Campaign

A motion of thanks was made and passed to the readers of the paper

E E SMITH, M D,  
Secretary

# THE DAILY PRESS

## THE NEWSPAPER IN PUBLIC HEALTH

Physicians recognize the power of the printed periodical in molding public opinion, and demonstrate their belief by supporting the official organs of their medical societies, and by supplying health news to the newspapers. An unintentional side light on the importance of the daily press in public health is contained in the following extract from an address of Frank E. Tripp, Manager of the Gannett newspapers, before the Rochester Ad Club, as reported in the *New York Herald Tribune* for June 10.

"I never heard of a citizen phoning the bill posters to hurry into his neighborhood with a billboard," he concluded. "I never heard of anybody seeking the removal of a postman because he failed to leave mail advertising literature. But let one newsboy miss a customer. From the most remote corner of the city comes a call, 'I didn't get my paper'."

"Out shoots a trouble boy on a motorcycle, delivering what? Delivering the most animate and perishable or all manufactured products, more valuable to peace and public safety than the Police Department, more necessary to business than the Chamber of Commerce, the poor man's university, the stabilizer of civilization, the guardian of public health—that abused, accused and damned necessity—the daily newspaper!"

It will be noted that Mr. Tripp says that one of the great functions of a newspaper in modern civilization is that of guarding the public health. He reveals the fact that the editors of newspapers depend on physicians and leaders of medical societies for medical news and for advice in matters of public health. Physicians do not have to ask for space for medical items. The editors will send for the news, and will put it in readable shape for the doctors. The editors will also show their gratitude by printing the doctor's name more prominently than some of his professional brethren think proper. But the editor must give the source of his information, and the standard way of doing it is to quote information in an interview. The physicians of New York State now make very few criticisms of those doctors who supply educational articles for the newspapers. On the other hand, physicians generally feel that the doctor who has a gift for writing educational articles should exercise it. Physicians are rather proud of one of their number who can write interesting items in the name of the Committee on Public Health of the County Medical Society.

The doctor of whom physicians are suspicious is the one who is outside the County Medical Society, and yet gets his name in the paper at every opportunity.

## SNAKE SERUM

There would seem to be but little call for "Serum for the Treatment of Snake Bites," by Raymond L. Ditmars, Curator of Reptiles in the New York Zoological Park (The Bronx Zoo), who is quoted in the *New York Herald Tribune* of June 20, as saying:

"Some persons feel all this talk of snake bites is far removed and even unreal. The fact is we have a call for serum constantly, and have in the last few weeks saved the lives of persons up state and in Pennsylvania by rushing serum to them."

The article was a news note to the effect that Dr. Ditmars was starting on a trip to Africa where he expected to visit an Algerian snake charmer who is immune to cobra venom. The article says further, in describing the potency of the immunity that may be acquired

"Dr. Ditmars revealed that at least one American, Col. M. L. Crimmins, U. S. A. (retired), has immunized himself against rattlesnake bites. This has been done so successfully that he has used his own blood as a serum when other persons in Texas were bitten and the emergency supply of regular serum had run out. The remedy was effective and scientists are studying the circumstances closely."

It is well for doctors to know that they can obtain a serum against snake bite from the New York Zoological Park in the Bronx, telephone Fordham 5560. The newspapers frequently carry spectacular descriptions of wild rides in autos and airplanes in order to rush a supply of the serum to bitten patients, and the story is usually one of success. See this JOURNAL, August, 15, 1926, page 729, and December 15, page 1053.

## PRESCRIBING ALCOHOL

The New York *Times* of June 2 comments on its Editorial Page on some inconsistencies of Tennessee and Indiana in prescribing alcohol for the Governors while denying it to other citizens. The editorial says

"Just now in Tennessee it appears that the physician in attendance upon Governor Peay, whose life was despaired of last February, pulled his patient through with ample doses of whisky. It was against the law, but when this fact was brought to the notice of the doctor, he coolly said that he 'didn't care' about that. What he was intent upon was saving the Governor's life, which he thinks he did."

"Tenderness for a Governor is shown in In-

diana by a proposal in the Legislature to relax the stringent Prohibition law of that State, so that a physician may give whisky to the Chief Executive, if it is thought desirable. No one apparently raises the cry that this would be class legislation of a grossly unfair kind.

"But are Governors such highly privileged beings? Is it not the proud boast of Americans that they are all sovereigns? What is good for a Governor is, on our theory of democracy, none too good for a garbage man. Let this fundamental principle be maintained, even if it carries with it the revolutionary notion that a doctor knows more about medicine than a member of Congress."

## THE PERILS OF BEAUTY SEEKING

The New York *Times* of June 6 has a readable editorial comment on the danger of beauty seeking, and says

"In the pursuit of beauty, ladies are valiant beyond all precedent. Frail creatures who tremble at the approach of a dentist will submit without the flutter of an eyelash to two hours in the clutch of a permanent wave machine. Doctors may warn them that cosmetics produced by wildcat companies are a peril, but they bravely face the risk. At the recent meeting of the New York State Medical Society the doctors were told that the widespread seeking for artificial beauty is more than a vogue and 'must be dealt with as a permanent matter.' It was urged that rou-

ges, lipsticks and hair dyes should come under the provisions of the Federal Food and Drugs act. London has had difficulties about the use of cheap cosmetics which prove poisonous.

"The feeling that 'there ought to be a law against it,' in the matter of suffering for beauty's sake, has actually been carried into action in French Africa. There dark-skinned beauties indulged in lip-stretching, nose-piercing and teeth-filing. The French Government long frowned on such activities, but now it has set a penalty of five to ten years in jail for those who carry beautification to the point of mutilation."

## THE COST OF LIVING

Physicians are vitally interested in the cost of living, for doctor's bills are about the last to be paid. High costs of living affect the medical profession sooner than almost any other group. The physician gets his full share of the benefits of the present industrial activity, and is now enjoying financial prosperity to a greater degree than he ever enjoyed before.

The cost of the necessities of life are far higher than they were before the World War, but the purchasing power of a day's work has increased still faster. This fact is brought out by the following item in the New York *Times* of May 31:

"While prices have remained on a comparatively high level, the family income goes about one-third further than it did at the beginning of the war before prices began to rise, according to the National Conference Board, 247 Park Avenue, in a statement yesterday.

"The purchasing value of the dollar as meas-

ured by living costs for the American wage earner and other persons of moderate means stands today higher than it was during the last two years, the board asserted, as the dollar is now worth, on the basis of present living costs, 61.1 cents as compared with the pre-war 1914 dollar. It was the lowest in July, 1920, when it stood at 48.9 cents.

"The purchasing power of the dollar,' the statement says, 'has been thus enhanced by the steady decline in average living costs throughout 1925 and 1926, which last April, however, were still 63.7 per cent higher than they had been in 1914, just before the war. But the average weekly earnings of industrial workers, owing to higher wage rates and more steady employment, at present are more than twice as high as they were in 1914, so that, in spite of the higher living cost, the wage earner on the average draws weekly pay of about 34 per cent, greater purchasing power than he did just before the war.'"

# BOOK REVIEWS

**CLINICAL SURGICAL DIAGNOSIS FOR STUDENTS AND PRACTITIONERS** By F. DEQUERVAIN Translated by J. SNOWMAN, M.D. Fourth English Edition. Octavo of 937 pages, with 750 illustrations and 7 plates. New York, William Wood and Company, 1926. Cloth, \$14.00

This is the fourth English edition of a volume that is well known in this country. The translation by Dr. Snowman is excellent, retaining for the English reader Professor deQuervain's practical expression.

There are over 900 pages, with 750 illustrations, and seven plates covering the subject of surgical clinical diagnosis. The basis for the entire work is the actual clinical experience of Professor deQuervain whose clinic has long been a shrine for those who have been fortunate enough to visit the University of Berne.

The changes in this edition as compared to the previous editions are chiefly in the diagnosis of surgical conditions in the brain, the kidney, and the thyroid gland.

The author who has long pleaded for the clinical study of the patient independent of the laboratory, gives us in this volume a stimulus at this time when we are so prone to overlook our clinical signs and accept the laboratory as the ruling factor in our diagnosis.

There is perhaps at this time no other one volume on this subject which gives the student of surgery as much practical information.

HERBERT T. WIKLE

**OUR DOCTORS A Novel of Today** By MAURICE DUPLAY 12mo of 279 pages. New York and London, Harper & Bros., 1926. Cloth, \$2.00

In the book there is combined not only an excellent fiction story, but a splendid delineation of a strong man's character and the influence of personal suffering on this character, and in addition a remarkable, though possibly somewhat exaggerated, portrayal of various types of practitioners, true not only in France but in any country. As to the medical facts and knowledge, especially pertaining to cancer research, one cannot but comment on their accuracy, for M. Duplay is the son of a physician and apparently well acquainted with the medical lore and history. "Our Doctors" is a book very ably translated and well worth reading.

W. H. RACHLIN

**THE PRACTICE OF MEDICINE.** By A. A. STEVENS, A.M., M.D. 2nd Edition, entirely reset. Octavo of 1,174 pages. Philadelphia and London, W. B. Saunders Company, 1926. Cloth, \$7.50

The second edition of this standard work on "The Practice of Medicine" contains the present views upon the subject. Because of the advances made in medicine since the publication of the first edition, the entire volume has been reset and much new subject matter introduced. The work is complete, thorough, accurate, well-written, ably presented, covers the wide field of internal medicine, and can be used profitably not only by medical students but by all who care for the sick.

The typographical work upon this volume of twelve hundred pages upholds the reputation of the publishers.

HENRY M. MOSES

**DISEASES OF WOMEN** By HARRY STURGEON CROSSEN, M.D. 6th Edition, revised and enlarged. Quarto of 1,005 pages, with 934 illustrations including one colored plate. St. Louis, The C. V. Mosby Company, 1926. Cloth, \$11.00

A review of this sixth edition is of value, not so much for the amount of new material, as that in fact must be limited, but for the very excellency of this book.

A logical arrangement of the material, clear cut verbal

pictures, excellent illustrations, and conservative judgment makes this book one of the most valued to the Gynecologist as well as to the General Practitioner.

G. W. P.

**PRACTICAL SURGERY OF THE JOSEPH PRICE HOSPITAL.** By JAMES WILLIAM KENNEDY, M.D. Octavo of 861 pages, illustrated. Philadelphia, F. A. Davis Company, 1926. Cloth, \$10.00

Doctor Kennedy has made out of his love for his old master a monumental book in which are discussed, with much prolixity, certain procedures and surgical principles of Joseph Price. Such are vaginal hysterectomy with clamps, now praised as the proper treatment for cancer of the cervix.

Appendicitis in which, among other things, Fowler's position is figured and discussed in complete ignorance of its theory, nature or practice.

Ectopic gestation, cervical and perineal repair, cystocele, tubal and ovarian infection.

Puerperal or wound infection.

Tubercular peritonitis. A chapter on drainage in abdominal surgery.

The Surgery of the gall bladder

Abdominal hysterectomy

The use of the Murphy button.

A horrible chapter on the surgery of breast tumors and others.

The book is to be considered a contribution to the history of surgery in the making of which the author and his master had no small part.

It is a fortunate fact that surgical education has advanced so rapidly, however, that no better propaganda for post graduate study could be accorded than is contained within its pages.

J. E. J.

**MIND AND ITS DISORDERS** A Text-Book for Students and Practitioners of Medicine. By W. H. B. SPENCER, M.D. 5th Edition. Octavo of 593 pages, illustrated. Philadelphia, P. Blakiston's Son and Company, 1926. Cloth, \$7.50

The book is divided into three parts. Part I, Normal Psychology, Part II, Psychology of the Insane, Part III, Mental Diseases.

In Part I is covered briefly the field of normal psychology, and its importance as a help and stepping stone to the study of psychotic processes is emphasized.

Part II is devoted to psychology of the insane and discusses the various abnormal psychological processes and paves the way to a better understanding of psychotic syndromes. Attention is drawn to certain disorders of perception, namely, the agnosias (aphasic phenomena), hallucinations and illusions. Further on, other aphasic features are touched upon such as apraxia and disorders of speech and writing. Under the heading of erroneous judgment various delusions with some psychological explanations are discussed. Finally, psychoanalytic methods are dwelt upon briefly and should serve to prepare the student for a better interpretation of the section on mental diseases to follow.

In Part III mental diseases are divided as follows: neurosis, the psychoneuroses, the psychoses, toxic insanity, organic insanities, idiocy and imbecility. While the terminology is somewhat different from the New York State Classification it seems to serve the same purpose.

The book is interesting and instructive. It should be helpful as a text for the student as well as a handy reference work for the practitioner.

A. E. SOPER

CLINICS, HOSPITALS AND HEALTH CENTERS By MICHAEL M DAVIS, Ph D Octavo of 546 pages New York and London, Harper and Brothers, 1927 Cloth, \$5 00

The author has had a splendid opportunity to make this extensive study in collaboration with the Committee on Dispensary Development.

The book will prove of value to all interested in the administration of clinics, hospitals and health centers

The work is based on an unusually wide study of actual conditions and contains much practical and helpful information

The publishers believe this to be the first book to deal intensively with this whole field and call attention to its value as a reference work A E

REPORTS OF THE ST ANDREWS (JAMES MACKENZIE) INSTITUTE FOR CLINICAL RESEARCH, ST ANDREWS, FIFE Volume 3 Edited by DAVID WATERSTON, M D Octavo of 227 pages, illustrated London and New York, Oxford University Press, 1926 Cloth, \$3 00 (Oxford Medical Publications)

These reports contain the results of the investigations of the several workers connected with this Institute founded by Mackenzie with the object of studying the earliest symptoms of disease, as well as the conditions which predispose to its occurrence, with a view to its cure and prevention A brief resumé and appreciation of the life and work of Mackenzie is given The importance of the capillary system in its relation to clinical symptoms is clearly reviewed by Bryson who feels that this part of the circulatory system has been neglected Many studies are presented of epidemics, more or less severe, in school children with the object of preventing these illnesses A paper upon the radiography of duodenal ulcer presents instructive pictures This volume shows the careful work being performed at this Institute HENRY M MOSES

THE TREATMENT OF CHRONIC DEAFNESS BY THE ELECTROPHONOÏDE METHOD OF ZÜNDBRUGUET By GEORGE C. CATHCART, M A., M D 12mo of 88 pages London and New York, Oxford University Press, 1926 Cloth, \$1 35 (Oxford Medical Publications)

This small volume deals with the problem of deafness and tinnitus, the study and treatment of which has been very discouraging to the otologist The author is very enthusiastic about its results, both from practice and personal experience in his own case of deafness The monograph deals with the problems, causation, prevention, and treatment of deafness The presence of adenoid tissue, in the author's opinion, is the starting point of progressive deafness that we see in adult life

The electrophonoïde method is a re-education method, various forms of which have been used for many years, beginning with the method of Itard and reaching its acme of development with Urbantschitsch of Vienna The electrophonoïde of Zündburguet reproduces the sound vibrations of the whole gamut of the human voice, and thus gives the requisite physiologic stimulus to the ear The sounds produced resemble those of the human voice extending over five octaves with vibrations between 80 and 3500 The quality of each sound can be varied as well as its intensity, the sounds being carried to the ear by telephone receivers The method of treatment is given in detail, with an excellent description of its uses and possibilities There is also a table setting forth the author's results which vary between 50% and 80% improvement in cases of nerve and middle ear deafness and in otosclerosis A wider use and treatment by this method is advisable in order to prove the claims of the author BENJAMIN H ABRAHAM

INFANT MORTALITY AND ITS CAUSES With an Appendix on the Trend of Maternal Mortality Rates in the United States By ROBERT MORSE WOODBURY, Ph D

Octavo of 204 pages Baltimore, The Williams and Wilkins Company, 1926. Cloth, \$3 50

This very complete inquiry into the cause of infant mortality is a detailed compilation of the material collected by the United States Children's Bureau, and Bureau of the Census The causes are disentangled and carefully analyzed in a very interesting way Reasons for the infant mortality of New Zealand, the lowest in the world, are carefully worked out, and the conclusions reached by the author are of great interest and are apparently unassailable A valuable book.

C. A. G

TRANSFUSION OF BLOOD By HENRY M FEINBLATT, M D Octavo of 137 pages, illustrated. New York, The Macmillan Company, 1926 Cloth, \$3 00

Dr H M Feinblatt's monograph on the transfusion of blood is a well written work on a timely subject. It contains all the essential facts necessary to a thorough understanding of the procedure, its contraindications and dangers Theoretical considerations are side-stepped, the greater part of the volume being devoted to the practical essentials A very extensive literature is incorporated in this volume

To those interested in the subject of transfusion, this book should be of great value. MAX LEDERER.

CHRONIC RHEUMATIC DISEASES Their Diagnosis and Treatment By F G THOMSON, M A., M D, and R. G GORDON, M D Octavo of 202 pages London and New York, Oxford University Press, 1926 Cloth, \$2 75 (Oxford Medical Publications)

The authors admit the inexactness of the term "rheumatism" but believe that the world has much to recommend it as the conditions discussed are allied and groups such as infectious arthritis, osteo-arthritis, fibrositis and gout merge into each other They believe that a scientific classification is not yet possible.

The book is divided into three parts, the first devoted to a discussion of the etiology, clinical types, differential diagnosis and of climacteric arthritis The second part describes some diagnostic difficulties and the third, various methods of treatment.

The etiological factors discussed are personal idiosyncrasy of unknown nature, cold and damp, undue fatigue, focal infection, strain and arteriosclerotic changes in the articular vessels

Fibrositis or muscular rheumatism is defined as an inflammatory reaction of the fibrous supporting tissue of the body to extraneous poisons which may be bacterial or toxic. A poison circulating in the blood is said to be present derived from the lower digestive tract or from some focus of infection Exposure to strain or to chilling are believed to be the chief contributing causes In the chronic cases nodules and fibrous bands may be felt which are the residual scar tissue resulting from the inflammatory reaction

Treatment is fully discussed and the book presents a satisfactory review of the subjects treated

W E. McCOLLUM

LOCAL IMMUNIZATION, SPECIFIC DRESSINGS BY PROFESSOR A. BESREDKA, Pasteur Institute, Paris Edited and translated from the French by DR. HARRY PLITZ, 216 pages, The Williams and Wilkins Company, Baltimore, Md., 1927, cloth, \$3.50

This small volume presents an interesting and fundamentally new point of view in the problem of immunity—namely, the idea of local immunity

Professor Besredka's conception is based upon long years of research and broad experience. In support of the viewpoint presented a large number of facts, both clinical and laboratory are cited The book is most interesting and provides food for much thought.

JOSEPH C. REGAN

**SELF-CARE FOR THE DIABETIC.** For the Use of Diabetic Patients. By J J CONYBEARE, M.C., M.D., 12mo of 70 pages. London and New York, Oxford University Press, 1926. Cloth, \$1.15 (Oxford Medical Publications.)

This is a small book which covers the usual subjects of importance to the diabetic patient. The part played by food in the body, a general description of diabetes, the usual diets, urinary tests and use of insulin are some of the subjects treated.

A useful feature of the book is a list of menus for the different meals offering a variety of foods of equal caloric value and another is a list of extras of "no food value."  
W. E. McCOLLUM

**SHELL SHOCK AND ITS AFTERMATH.** By NORMAN FENTON, Ph.D. With an Introduction by THOMAS W. SALMON, M.D. Octavo of 173 pages. St. Louis, The C. V. Mosby Company, 1926. Cloth, \$3.00.

A careful follow-up study of the soldiers shell-shocked during the War is recorded. As the psychoneuroses and neuroses of military life are essentially the same as these conditions among civilians, differing mainly in degree, this book should be of interest to students of psychology and psychiatry.  
FREDERIC DAMRAU

**STUDIES IN PSYCHOLOGY AND PSYCHIATRY.** From the Catholic University of America. Edited by EDWARD A. PACE. Vol. I, No. 1. The psychology of Reasoning. By MIRIAM FRANCES DUNN. Octavo of 141 pages. Vol. I, No. 2. Diastatic Activity of the Blood Serum in Mental Disorders. By JOHN WILLIAM RAUTH. Octavo of 32 pages. Baltimore, The Williams and Wilkins Company, June, 1926. Price per volume, \$5.00.

Numbers 1 and 2 of the Studies in Psychology and Psychiatry include monographs covering the subjects of the psychology of reasoning and the diastatic activity of the blood serum in mental disorders. These subjects are well handled and should prove interesting reading to all who are in search of information on those topics.  
FREDERIC DAMRAU

**THE TREATMENT OF THE ACUTE ABDOMEN.** Operative and Post-Operative. By ZACHARY COPE, B.A., M.D. Octavo of 238 pages, illustrated. London and New York, Oxford University Press, 1926. Cloth, \$3.50 (Oxford Medical Publications.)

"This book," says the preface, "is a companion and complement to the Early Diagnosis of the Acute Abdomen." It does not appear to this reviewer to be a worthy fellow of that excellent little work.

The author attempts, in the first place, an impossible task—to produce in 232 pages an account of the operative surgery of the acute abdomen. In the second place he wastes space in reprinting, from instrument makers' catalogues, pictures of forceps, knives and scissors—of operative procedures scarcely less final and in diffuse and unnecessary verbiage.

In the third and last place it is full of dogmatic half-truths and of naive antiquity.

Not so good

J. E. J.

**AVIATION MEDICINE.** By LOUIS HOPEWELL BAUER, A.B., M.D. Published by authority of the Surgeon General. Octavo of 241 pages, with illustrations. Baltimore, Williams and Wilkins Company, 1926. Cloth, \$7.50.

This book takes up, in a very comprehensive way, the medical requirements of a flier. First, the general physical requirements are considered, and then, the more important special organs such as the ear, eye, nose, throat, heart, lungs, etc.

All the special examinations that are used to test altitude, depth, perception, equilibrium, etc., are clearly described and accompanied by appropriate pictures and charts. For anyone interested in aviation and aviators, from the medical standpoint, this book is an ideal one. The fundamentals are present and in a readable manner.

KENNETH MACINNES

**THE FAITH, THE FALSITY, AND THE FAILURE OF CHRISTIAN SCIENCE.** By WOODBRIDGE RILEY, Ph.D., FREDERICK W. PEABODY, LL.B., CHARLES E. HUMISTON, M.D. Sc.D. Fleming H. Revell Co., New York, 1925.

This exposé of Christian Science, neatly done in 404 pages, by three gentlemen who, possessed with facts, know how to express themselves, is recommended to physician and layman alike.

Dr. Riley writes on the Faith of Christian Science. He covers the personal sources, the problem of plagiarism, Quimby, the discoverer, the Medicine Man, the Occultist, from mind healing to metaphysics, Alcott, the inspirer, mysticism, divine science, marriage and sex, and psycho-analysis.

Frederick W. Peabody deals with the Falsity of Christian Science. His chapter headings are Autocracy, Autocrats, Suppression, Swindling, Lies, Death, and Cash.

Dr. Humiston concludes the book with the Failure of Christian Science. His chapters include Christian Science—A Medical Parasite, Deceit, The "Cures" of Christian Science, The Failures of Christian Science, and Conclusion.

Recently a member of the reviewer's family "turned" to Christian Science. Patiently, we permitted frequent visits of the "practitioner" and submitted to "absent treatments," all at so much per, in real coin of the land. This entertaining and instructive and revealing volume, brought home for review, chanced into the sick one's hands. It was read from cover to cover. When we arrived home that evening, we were met with, "I wish I could sue that woman (the practitioner) for cheating me—to think I was so gullible as to be ensnared if every one read that book (The Faith, The Falsity, The Failure of Christian Science) there would be fewer victims to be stung. In your review recommend every adult of normal intelligence to read it."

And that we earnestly do

T. S. W.

**BIRTH CONTROL AND THE STATE.** A Plea and a Forecast. By C. P. BLACKER, M.C., M.A., 16mo of 87 pages. New York, E. P. Dutton and Company, 1926. Cloth, \$1.00.

This is one of the To-day and To-morrow Series, a series of small monographs on scientific and philosophic topics.

The author presents the chief arguments for and against birth control from the personal, social and international aspects. Due to his nativity his viewpoint is British. His fear that unless birth control is adopted there will be another world war starting with hostilities between the United States and Japan is certainly interesting although not convincing to the reviewer.

E. H. M.

**WERK UND WIRKUNG—Eine Vortragsreise.** Von Professor Dr. HANS MUCH. 12mo of 227 pages, illustrated. Leipzig, Curt Kabitzsch, 1926. Paper, Marks 7.20 (Moderne Biologie, Heft 11).

A small volume of lectures on various interesting phases of medicine, delivered while on a tour by a scientist. The reading of this collection of lectures emphasizes the broadness of mind, the generous philosophy and the literary ability of a well known authority in the biological field.

MAX LEDERER.

# OUR NEIGHBORS

## THE IDEALS OF THE JOURNALS OF STATE MEDICAL SOCIETIES

The question "What are the ideals and standards of the Journals of State Medical Societies?" is well discussed in the following editorial from the June issue of *Colorado Medicine*—EDITORIAL NOTE

"A state journal is in no sense a literary competitor of national or specialized periodicals. When it ceases to be local in its sphere of interest it surrenders its first right to existence. Occasionally we are appraised of the laments of a well wishing confrere regarding the type of some of the material that is given space in *Colorado Medicine*. Our lacrimation is often quite as copious and our laments quite as loud. Our culpability, however, consists in our policy of publishing the transactions of the State Society and a few other articles submitted by society members. To do better involves certain technical difficulties inherent in the perennial problem of lifting ourselves by our own boot straps. When medicine is more uniformly practiced on the highest scale and always recorded in faultless diction, then and only then will all of our articles be above this just criticism.

"'But,' laments the lover of good literature, 'why is not the material culled and selected?' This is a pertinent query indeed, but is answered by the statement that occasionally no selection is possible. If, for example, six articles comprise a journal and only six are at hand, the selection may be ever so painful but always easy.

"'But,' continues our grief-stricken reader, 'why is such a situation permitted to arise when the Society has many members who are always able and willing to make credible literary contributions for the asking?' This is exactly what is often done with distinct value to the general average of our literary efforts. But such contributors do not represent the whole of literary thought. Our relatively silent members practice the same art, pay the same dues and are consequently entitled to the same privileges of the Society. If our columns are open only to the mature and experienced

writers, where, we ask, can others make a beginning?

"'But,' wails the over-anxious stickler for scientific exactness, 'much damage is done by the publication of ambiguous and erroneous data.' To this we agree if the journal is widely and carelessly read, but, that granted, our columns are always open to a courteous refutation of error, an approved method of exchange of ideas by which medical thought is often best promoted.

"We are thoroughly in sympathy with the demand for a higher standard of excellence if it can be had without too great sacrifice of other important ideals, but after reviewing most of the state and sectional medical publications, we are convinced that it is more to the point that these publications reflect the thoughts and activities of the rank and file of practitioners, a round-robin, as it were, of local professional interest. For this apparently good reason space is as freely accorded the country doctor as the college professor. A generous supply of personal news notes, county society proceedings and timely correspondence is within the reach of every member and serves the purpose of *Colorado Medicine* quite as appropriately as lengthy, original articles of which there is abundance in journals of a distinctly different type.

"It is our hope that a much larger number of our members may acquire the habit of submitting short, original papers for publication. Excellent guides are available for perfecting the art of medical writing, most notable of which are 'The Art and Practice of Medicine Writing' by George H. Simmons, and Dr. Morris Fishbein, and 'Suggestions to Medical Authors' or A M A Style Book. Now that many manuscripts are in the making for our next annual meeting many of us would do well to consult such authoritative counselors. By thus producing more acceptable papers we would give less cause for grief to those lovers of literature who sit on the river shore and make only a briny contribution to the waters of Babylon."

## ANNUAL MEETING OF THE MISSOURI STATE MEDICAL ASSOCIATION

The physicians of New York State will be interested in the annual meeting of the medical organizations of other states. The May issue of the *Journal of the Missouri State Medical*

*Association* comments on the recent meeting of the society as follows:

"The 70th annual session of the State Medical Association (Continued on page 750)

# In the Broadest Sense . . . . .

*"Nutritional disturbances are due to a disproportion between the nature of the food and the ability of the organism to digest and assimilate"*

—Abt's "Pediatrics"

Restlessness, vomiting, loss of weight, are all manifestations of subnormal development and Pediatricists generally agree that almost every abnormal phase of infant life is closely linked to the subject of nutrition.

Clinical observation of infants and children over a period of many years conclusively proves that by virtue of the flocculent condition of the curd, DRYCO presents an optimum mixture for the physiological processes of digestion and consequently more easily satisfies nutritional requirements.

The later nutritional defects so frequently evident in the artificially fed, rarely manifest themselves in those infants fed exclusively with

# MAMMALA

## The Only Scientifically Modified Milk for Babies and Invalids

MAMMALA is pure fresh cow's milk of the best quality, modified for Babies, Children and People of All Ages by removing a part of its cream and by adding a suitable proportion of milk-sugar, and then dried rapidly by the scientific process of HATMAKER, which kills all disease germs that may be present and makes it safe and preservable. It is composed entirely of milk constituents and does not contain any starch, malt, cane-sugar, bicarbonate of soda or other foreign substance. It is a very nutritious, balanced, complete food which is easily digested and very completely assimilated.

cal Association passed into history at Sedalia, May 5, with the record of having been one of the most successful, interesting and harmonious meetings the organization has enjoyed.

"In the House of Delegates the new constitution and by-laws were adopted with few alterations. One important change was a provision to accept new members at one-half the amount of the regular annual dues for the first two years subsequent to graduation. This provision was adopted in order to permit those societies who have been admitting such graduates at one-half the regular dues of the component society to pay only one-half of the State Association dues.

"Dr C A Vosburgh, St Louis, reported as a special representative of President Breuer on the conference held at Memphis, Tennessee, April 28, with the American Red Cross to discuss the flood situation in the lower Mississippi Basin. At the time of the conference it was shown that there were approximately 175,000 homeless refugees concentrated in emergency camps. Dr Vosburgh promised the conference, in behalf of Missouri, a quota of 250 physicians if that number were needed.

"Dr Guy B Mitchell, a member of the State Senate, called attention of the House to a resolution adopted by both branches of the General Assembly creating a commission to survey the state and investigate the needs of the crippled children of Missouri, and stated that such commission had been appointed. He also stated that the bill providing for hospital care and education of crippled children at the State University had been approved by Governor Baker and that the Governor had approved and released an appropriation of \$35,000 to enable the University to begin the work of providing for these children.

"The Pettis County members were indefatigable in providing entertainment for the visitors and the preparation of facilities for conducting the meeting, having always one or more members on hand to make every one feel at home. The entertainments were most pleasant, the reception and dance following the addresses of the president and guests being well attended and the call for ladies as partners for the men visitors at the dance was over supplied. The sporting element among the visitors were highly entertained by the boxing match on Tuesday night and the numerous special parties filled out a series of entertainments that left no one neglected.

"The dinner to the county society secretaries was by far the most enthusiastic and the most enjoyable of any that has ever been held. There were 52 guests including councilors, presidents and secretaries of county societies, and officers of the State Association. Dr J T

Hornback deserves great credit for having arranged for such a splendid meeting

"The total number registered at the meeting was 337, a few less than the number Dr Ferguson had determined should be present, for he had made up his mind to bring up the total to 400"

### SPONDYLITIS DEFORMANS

It is rather common to see a person whose back is bent forward to an extreme degree. Many of these persons walk the streets, objects of pity and the victims of every fakir who comes to town. The streets of a small Pennsylvania village were recently thronged with such cripples attracted by the offer of a free treatment by a travelling fakir who received the applicants in royal state

The May issue of *Northwest Medicine*, the organ of the state medical societies of Oregon, Washington and Idaho, explains the conditions in an article by Dr Paul N Jepson of the Mayo Clinic, from which the following abstracts are taken—EDITOR'S NOTE

"Spondylitis deformans is a chronic progressive disease of the spine, beginning with painful stiffness and terminating in complete rigidity and a variable degree of deformity. The etiology is the same as in any case of chronic infectious arthritis

"The patient usually complains of a lame back, especially on arising in the morning. It may be stiff for some time before movement causes relaxation. As the disease progresses the pain becomes gradually more and more aggravated by bending, moving or riding

"As a rule, the disease progresses to the dorsal spine and finally, although not always, to the cervical spine. As a portion of the spine becomes ankylosed, the pain decreases in that part. The disease need not progress in this order for there are not a few cases of primary cervical involvement

"When the cervical spine is involved, movements of the head and neck become painful and the head may drop forward on the sternum

"The diagnosis of spondylitis deformans should not be difficult, however, one must always bear in mind the possibility of tuberculosis, malignant disease, an old fracture or sciatica neuritis

"There will not always be positive roentgen-ray findings, but this need not exclude spondylitis, for in many cases the disease has not progressed far enough to show bony changes by the roentgen-ray. Then, too, there is the type in which bony hypertrophy is absent

"When the roentgen-ray findings are posi-

(Continued on page 752—adv. xviii)

## Children Really Like This Pleasant Tasting Cod Liver Oil

When the physician prescribes cod liver oil, the administration of the oil is not always easy

This is not a problem, however, when PATCH'S FLAVORED COD LIVER OIL is prescribed. Children (and older folks, too) really like it.

We had the patient in mind when we conceived the idea of adding a slight amount of flavoring to our vitamin-tested cod liver oil. This won immediate favor because it solved a real problem

Owing to its high vitamin potency, the dose is small—one-half teaspoonful for children or one teaspoonful for adults. To guarantee the high vitamin potency, every lot of oil produced in our plants is biologically assayed in our laboratory

The pleasant taste and the small dose make PATCH'S FLAVORED COD LIVER OIL a most desirable product.

If you wish to become better acquainted with this "different kind" of cod liver oil, mail the coupon below for a sample and interesting literature

(Continued from page 751)

tive, they show loss of the intervertebral disc and there is parrot-beak lipping of the edges of the vertebrae. This is almost pathognomonic of spondylitis. In many cases there is a solid deposit of bone between the vertebrae, giving them the appearance of being soldered together. It is always well to have a lateral as well as an anteroposterior view of the spine so that fracture or destruction of a vertebral body may be excluded.

"In the absence of positive roentgen-ray findings, one must rely pretty much on the history and on a thorough physical examination. Usually the stature is highly suggestive.

"The accepted form of treatment has not been materially changed for many years. As a rule the patient is given instruction about exercises and the application of heat, and then equipped with some type of a back brace. If there is a focus of infection, its removal is advised in the hope that thus the exciting cause will be removed. In a good many cases this form of treatment gives surprisingly good results, but there still remains a group that apparently resists every attempt at improvement. In this type total kyphosis of the spine has usually developed and the patient when first seen is bent over and partially incapacitated. This is the type most often seen at the Mayo Clinic, and its treatment has indeed been discouraging.

"For the last year we have been carrying out a slightly different form of treatment. The patient is treated for about a week with diathermy. Intensive through-and-through treatment is required and it is important to cross-fire whenever possible. Bone offers more resistance to the passage of the high-frequency current and is very slow to heat, but it retains the heat for hours, slowly giving it up to the surrounding tissues. The minimal period of treatment is thirty minutes, but it is extended to forty-five minutes whenever possible. The size of the electrodes and the method of applying them will vary with the part of the spine involved. The length of each treatment and the position in which the patient is placed are important details. Pain is usually markedly relieved within the first three or four treatments. After this, stimulation and exercise of the muscles of the spine are begun by means of an evenly surging sinusoidal current. Very small active electrodes permit the different muscles to be picked out and exercised separately. The number of contractions should seldom be more than ten a minute. The time of application is gradually increased not to exceed five minutes, but it is desirable to keep the daily average around three minutes. When polarity as well as exercise is desired the pul-

sating direct galvanic current may be substituted for the sinusoidal."

The author also describes exercises and the forcible extension or stretching of the spine by means of weights or other forms of pulling.

As for results the author states that in a series of thirty-seven cases treated at the Mayo Clinic, the results were as follows:

Thirty-nine per cent showed no improvement.

Sixteen per cent were relieved of their pains, but their deformity was not much improved.

Forty-five per cent were relieved of pains and their deformity was distinctly improved.

The treatment of cases is largely a community problem. There must be a hospital or dispensary well equipped to give the treatments, and there must be a social service and educational facilities in order to induce the patients to persist in obeying their medical advisors. These cases are striking examples of the mutual interdependence between physicians and voluntary organizations engaged in public health.

## THE BLEACHING OF FLOUR

The London letter of the *Journal of the American Medical Association* of June 11, contains the following discussion of the bleaching of flour—  
EDITORIAL NOTE.

"Flour, after milling, changes slightly on keeping, its baking qualities improve, and its coloring matter is bleached. This natural aging is probably an oxidation process. Imported flour from America and Australia is kept sufficiently long to exhibit this aging effect.

"The higher grades, which are obtained from the hardest part of the endosperm, called the semolina, are not only harder but produce a lighter colored flour. These are known as 'white' or 'patents,' and total about 50 per cent of the flour milled, the remainder are known as 'households.' From the latter and softer flour the offal is less perfectly separated. By the use of bleaching a proportion of the 'households' can be made to simulate patents, and a 'longer range of patents' can thereby be obtained. Chlorine bleaches by combining with the coloring matter of the flour (carotin), but it also combines with other constituents of the flour. It can act on the tyrosine and tryptophan groupings of the gluten complex with injurious results. The vitamins in flour are very susceptible to traces of chlorine and may be destroyed. Nitrogen trichloride has a sim-

(Continued on page 754—ad xx)

# METABOLISM TESTING—

*how it will help you!*

You'll get from Metabolism Tests just the help you want in diagnosing perplexing Borderline Cases in checking up your X Ray and Iodin Treatments in deciding whether or not certain patients are good Surgical risks!

## Are the Tests Simple?

Yes with the latest Sanborn Metabolism Tester you or your assistant can make the test and get the Basal Metabolic Rate in less than 15 minutes without any complicated figuring.

Every detail is automatically recorded on a Kymograph chart that shows what occurred during each minute of the test and the patient's Actual Oxygen Consumption.

The Kymograph is an integral part of the Sanborn Graphic. It simplifies testing and makes results accurate and dependable. Well worth your while to learn more about it.

## A New Booklet

Dr.

Street

City and State

(Continued from page 753)

ilar action but is much more reactive than chlorine, and therefore less of it is used Benzoyl peroxide, after bleaching the coloring matter in the flour, remains as benzoic acid, and although the amount is small, it is better that flour should not contain benzoic acid Nitrogen peroxide, like the other bleachers, oxidizes the carotin in the flour It is less reactive with proteins and fats than chlorine, it leaves nitrites in the flour, though very little The committee regards nitrogen peroxide less unfavorably than the other bleaching agents The substances used as 'improvers' are principally chlorine, nitrogen trichloride, acid calcium phosphate, acid ammonium phosphate, and persulphates, besides extracts of malt and wheat germ It is claimed that 'improvers' enhance the natural baking qualities of flour by yielding well risen loaves of good volume and symmetry, of satisfactory texture, and of even aeration

"Strength" is the term applied to flours possessing this character, and it depends on

the qualities of the contained gluten Some wheats are 'weak,' but the properties of the gluten can be altered by the addition of certain salts and acids It is claimed that by the use of 'improvers' a more varied supply of wheats can be used and blended, and a flour of uniform baking quality thus maintained It is claimed also that the 'improver' promotes the growth of yeast and so improves aeration How improvers act is more difficult to define, one important factor is the degree of acidity It is known, for example, that acid phosphates cause dispersed gluten to cohere, but another explanation ascribes the gluten change to oxidation

"It should be compulsory for the manufacturers of chemical substances for use either as bleaching agents or as improvers or both to declare the nature of the ingredients of which they are composed, and that millers should be required to inform their customers whether their flour has undergone a process of chemical bleaching or improving or both, and if so, with what substances and in what proportion"

## A PERFECT MEAL

What is a perfect meal? The question is answered briefly and concretely by Dr E E Cornwall in the May issue of the Long Island Medical Journal, from which the following abstract is taken—*Editor's Note*

"A perfect meal is one which supplies a sufficiency of food for its portion of the daily ration, which is properly balanced as to its food principles, which is easily digested and assimilated and which is palatable. Within the range of this definition an infinitude of perfect meals can be found. I select for an example the following meal, which has among its merits simplicity of structure and cheapness (its ingredients cost less than twenty-five cents)

"A large bowl of whole wheat bread and milk and one or two apples or similar fruit, or, stated in definite quantities, a pint of milk, four ounces of whole wheat bread and eight ounces of fresh fruit

"This meal has a fuel value of about 800 calories. It contains nearly 30 grams of protein, more than half of which is 'perfect' protein, about 20 grams of fat, and about 125 grams of carbohydrate. Its mineral content is satisfactory as regards varieties and quantities, calcium is supplied particularly by the milk, and phosphorus particularly by the whole wheat. It contains good quantities of vitamins, Vitamine A being supplied particularly by the milk, Vitamine B particularly by the milk and the whole wheat, Vitamine C particularly by the fresh fruit, Vitamine D particularly by the milk and whole wheat, and Vitamine E particularly by the whole wheat

"It is digested easily by most people, if difficulty exists in regard to the digestion of milk it can generally be obviated by modification or substitution of proper equivalents

"It is easily assimilated, and being favorable to the development of the acid forming as

This unqualified guarantee goes with each and every carton of

Prepared Casein

## Dietetic Flour

More of this Flour is prescribed by New York State Physicians than anything else of its kind. The variety of foods that are so easily made in the patient's home are both palatable and attractive. Lister's Flour is self-rising and a Recipe Booklet is in each carton.

and

**LISTERS, Limited**  
Huntingdon, P. Q., CANADA

against that of the putrefactive types of bacteria, as well as purin free, it is well suited for inclusion in an 'easy diet' and has hygienic advantages

"It is reasonably palatable, a liking for it is not difficult to acquire, and one does not tire of it

"This meal can be varied considerably without essentially changing its character, by modification, substitution of equivalents and rearrangement of its elements

"Among the different forms in which this meal may be served are the following: a A bowl of bread and milk with fruit on the side b A bowl of bread and milk and berries c A large glass of skimmed milk or buttermilk with bread and butter and fruit d Cheese sandwiches with fruit e Bread and butter with cream cheese, fruit salad. A convenient and generally acceptable form in which it may be served is as a bowl of bread and milk with baked apple. In the form of a bowl of bread and milk and huckleberries it should appeal to an epicure."

This formula for a perfect meal is offered without prejudice to other perfect meals. It is fitting and proper that the diet should be as varied as circumstances permit, the pleasures of the table are legitimate within bounds, a combination of meat, potatoes, bread and butter and salad may also be a perfect meal. The meal here described has a place in the dietary of both health and disease.

For the pint of whole milk may be substituted as approximately equivalent in protein content and not notably different in quality, the following: A Skimmed milk or buttermilk, 16 ounces, with butter,  $\frac{3}{4}$  ounce B Cottage or pot cheese (curd),  $2\frac{1}{2}$  ounces, with butter 1 ounce C American, Swiss or full cream cheese, 2 ounces, with butter,  $\frac{1}{3}$  ounce D Whole milk, 8 ounces, with cottage cheese, 1 ounce, and cream, 2 ounces E Whole milk, 8 ounces with American, Swiss or full cream cheese, 1 ounce

(Continued from page 753)

lar action but is much more reactive than chlorine, and therefore less of it is used. Benzoyl peroxide, after bleaching the coloring matter in the flour, remains as benzoic acid, and although the amount is small, it is better that flour should not contain benzoic acid. Nitrogen peroxide, like the other bleachers, oxidizes the carotin in the flour. It is less reactive with proteins and fats than chlorine, it leaves nitrites in the flour, though very little. The committee regards nitrogen peroxide less unfavorably than the other bleaching agents. The substances used as 'improvers' are principally chlorine, nitrogen trichloride, acid calcium phosphate, acid ammonium phosphate, and persulphates, besides extracts of malt and wheat germ. It is claimed that 'improvers' enhance the natural baking qualities of flour by yielding well risen loaves of good volume and symmetry, of satisfactory texture, and of even aeration.

"Strength" is the term applied to flours possessing this character, and it depends on

the qualities of the contained gluten. Some wheats are 'weak,' but the properties of the gluten can be altered by the addition of certain salts and acids. It is claimed that by the use of 'improvers' a more varied supply of wheats can be used and blended, and a flour of uniform baking quality thus maintained. It is claimed also that the 'improver' promotes the growth of yeast and so improves aeration. How improvers act is more difficult to define, one important factor is the degree of acidity. It is known, for example, that acid phosphates cause dispersed gluten to cohere, but another explanation ascribes the gluten change to oxidation.

"It should be compulsory for the manufacturers of chemical substances for use either as bleaching agents or as improvers or both to declare the nature of the ingredients of which they are composed, and that millers should be required to inform their customers whether their flour has undergone a process of chemical bleaching or improving or both, and if so, with what substances and in what proportion."

## Four Cylinder Tankless Adjusto Outfit Model No. 454

ADJUSTO OUTFIT  
No 454

For the man who does not specialize in ear, nose and throat work, we have built this general outfit, comprising of an anesthesia combination, if necessary, sinus cleanser, spray set, waste receptacle, and with separate positive and negative pressure, both under perfect control.

## ARSENIC FINDINGS IN DERMATOLOGICAL CONDITIONS\*

By BINFORD THRONE, M D, L S VAN DYCK, M D, ELEANOR MARPLES, A.B, AND  
C N MYERS, Ph D

From the New York Skin and Cancer Hospital, New York, N Y

**A**RSENIC is one of the oldest drugs used in medicine. The ancients knew two sulphides of this metalloid, Realgar, the red sulphide,  $As_2S_2$  and Orpiment the yellow sulphide,  $As_2S_3$ .

The earliest record of the use of arsenic in medicine is found in Rasaratnasamuchchaya, an East Indian materia medica dated 1300 B C. In this work Orpiment is recommended in the treatment of leprosy. It also contains a receipt for a mixture of arsenic and pepper to be used in intermittent fever. This seems to have been the fore runner of our present Asiatic Pill Hippocrates (460-377 B C), Aristoteles (384-322 B C), Dioscorides (40-90 A D) and Avicenna, the great Arabian physician all knew and recommended arsenic in the treatment of various diseased conditions.

For many years it has been known that the internal administration of arsenic could cause inflammatory disturbances of the skin and nerves. The skin condition could vary from a simple erythema to a generalized exfoliative dermatitis, and from vesicular and bullous eruptions to those causing gangrene. From its long continued use a variety of lesions have been described, the most characteristic of which are keratosis and pigmentation. Hyperkeratosis of the palms and soles with thickening of the nail bed and changes in the nails are frequently seen. Psoriasiform lesions of the dorsa of the fingers and near the elbows have been described<sup>1</sup>. The possibility of malignant degenerations occurring in arsenical keratoses is well known. Leitch and Kennaway<sup>2</sup> were able to produce a wart upon the epilated skin of a rat by the external application of a 0.12 per cent arsenious acid. The wart later degenerated into a typical squamous cell carcinoma. Bavet and Slosse<sup>3</sup> as the result of the analysis of factory dust supported the arsenical causation of industrial carcinomata. W J O'Donovan reported<sup>4</sup> three cases of occupational

arsenical cancer seen at the London Hospital. O'Donovan quotes from the Pharmacologia of John Ayrton Paris, fourth edition, 1820 "It may, however, be interesting and useful to record an account of the pernicious influence of arsenic fumes upon organized being as I have been able to ascertain in the copper smelting works and tin burning houses of Cornwall. This influence is very apparent in the conditions of both animals and vegetables of the vicinity, horses and cows commonly loose their hoofs, and the latter are often to be seen in the neighboring pastures crawling on their knees and not infrequently suffering from a cancerous affection of their rumps — It deserves notice that the smelters are occasionally affected with a cancerous disease of the scrotum similar to that which infests chimney-sweepers." This is the earliest reference to the relation of occupational contact with arsenic as a causative agent in dermatological conditions, that we have seen.

Since the introduction of the arsphenamines in the treatment of syphilis and the skin reactions caused by them an intensive study has been made to explain the mechanism of these reactions and to develop a plan of treatment for their relief. During the last year and a half we have directed our efforts to determine a possible relationship between arsenic intoxication and various dermatoses. The initial cases to direct our attention to this line of work were reported in a previous communication<sup>5</sup> together with the diagnostic procedure. In one of these cases the arsenic had been given for medication, in the other one the arsenical intoxication had been acquired through absorption through the skin following the long continued use of calamine and zinc lotion. This lotion on analysis showed 0.84 mgs of arsenic per 100 gmms of dried specimen.

In this paper we will give our arsenic findings in various dermatological conditions and try to explain its action.

Scleroderma,

This condition has been one of the many mys-

## COLOSTOMY APPLIANCES

Within the last 10 years, the technique of colonic operations has been so wonderfully developed that thousands of patients have been saved. In order to assist those patients after the operation has been successfully performed, it was necessary to devise a Colostomy Pouch, which the patient can wear with comfort, in order to keep his body perfectly clean, and also supply him with an appliance which can be kept sterile.

THE WILLIAM M EISEN COMPANY, after several years of experimental work, finally succeeded in perfecting a Colostomy Pouch, which has all the qualities and advantages required for that purpose.

THE EISEN COLOSTOMY POUCH is made with a pneumatic soft rubber cushion inter changeable receptacles, a very light non-rustable metal cup, and an elastic adjustable body belt which is detachable from the Colostomy Pouch. The cup and pouch which lies over the artificial rectum can be easily cleaned, and there is no possibility of any leakage between the pouch and the opening of the artificial rectum, when applied to the body.

This pouch is recommended by a great many leading Surgeons all over the country, and recognized as a most satisfactory appliance. See advertisement on page xxii—Adv

## MAMMALA CORPORATION

We are pleased to have Mammala return to our advertising columns. It was the original dry milk for Babies and Invalids and it has given the users great satisfaction for over twenty years—See advertisement, page xvi

COLOSTOMY POUCHES  
No 3000

This apparatus for artificial Anus is the most sanitary and practical of its kind. The body plate and drain funnel are of white metal and a pneumatic ring between body of plate and plate serves to make the latter cling close to the body. Two rubber pouches of the necessary size are supplied in order that one may be thoroughly cleansed and discarded while the other is in use.

RECEPTACLE FOR NATURAL ANUS  
With Body Belt

The only appliance made for the non-retention of stool. Will take care of the natural discharge in a cleanly and efficient manner. Made entirely of soft rubber assuring comfort to patients.

SUPRA PUBIC DRAINAGE APPLIANCE  
An apparatus devised for the purpose of receiving the Urine while drainage is taking place after a bladder operation.

her a great deal of candy The only canned food eaten was canned peas

The arsenic findings in this case were extraordinarily high At times being over 30 mgs per gmms of dried specimen or more than 100 times the normal amount

This patient was lost track of and we do not know her present condition

Below is the arsenic report of her urine

No 5 Female, adult The condition began on the knees and next appeared on the ankles, next the lumbar regions became involved Later the hands, face, neck and feet were affected

This patient had worked with a furrier and the absorption of the arsenic had taken place as the result of handling furs which had been sprayed with arsenic

The results of treatment with sodium thiosulphate were exceptionally good, the patient being practically cured

Below will be found the report of the arsenic findings in this case

No 6 Male, Jewish, aged 4 years Duration of the condition several months The lesions began on the buttocks and later appeared on the neck and trunk They were markedly pigmented and followed nerve distribution This case was much improved by treatment

Below will be found the arsenic findings

The other three cases were similar in their clinical symptoms and the arsenic findings corresponded to those reported within the six cases described above

teries of dermatology as to its causation. A rational treatment has been equally obscure.

All kinds of causes have been assigned to it from exposure to cold and wet to changes in the central nervous system. Hyper and hypo function of all the endocrines have been described as accompanying the process, at times the same patient showing both conditions. In a most excellent review of the endocrines causation of this condition Castle<sup>6</sup> in his conclusions says "Out of the very large amount of literature which has appeared on the subject of scleroderma there is very little which helps to any great extent in the elucidation of its aetiology." As to its association to a deficiency of the internal secretions he says, "In most of these cases the deductions are founded on a misconception. It is surely erroneous to suppose that because the extract of a gland may improve or even cure a case, the underlying cause of the disease was a deficiency of this gland." He groups trauma and irritation together and says "however it seems probable that damage to the skin and subcutaneous tissues may predispose the subject to scleroderma if there are any other influences present which would by themselves tend to produce scleroderma." "From the consideration of my own and the many published cases, I consider that the essential cause of scleroderma is a combination of a disordered function of the internal secretory glands, together with an affection of the nervous system. It is more probable that the internal secretory system acts as a whole and if any particular gland fails, the remainder act in a way to minimize that failure and so, it is impossible to fix the responsibility on any gland."

While Castle says that an affection of the nervous system is most probable, he does not make any statement as to whether this affection is primary or whether it is secondary to endocrine dysfunction.

Ayers<sup>7</sup> in 1920 reported three cases of scleroderma in whose urine arsenic was found. He pointed out the similarity of its symptoms to those of arsenic poisoning, especially in its neuritic symptoms and pigmentation.

Cockayne<sup>8</sup> considered it a trophoneurosis due to disease of the vegetative nervous system. The prodromal symptoms of scleroderma, erythema, pains, pigmentation, transient attacks of local asphyxia as are seen in Ranaud's disease, he thinks support this view.

In our series of 9 cases, we had no case which began on the head or neck except one. All cases except one were asymmetrical. In all cases the inguinal region was involved to a more or less extent. This inguinal involvement was characterized chiefly by pigmentation, the more severe changes, which were present on the other parts of all the patients were not so marked in this region, and the final atrophy in this region was always slight. In some of the cases the absence of pigmentation

around the hair follicles was clearly marked. In each patient the location of the lesions definitely followed nerve distribution.

In each case arsenic in pathologic amount was found in the urine following the injection of sodium thiosulphate.

The following is a brief history of some of these cases and the arsenic findings in their urine.

No 1 Betty G, this case was reported in detail in the *Archives of Dermatology*, Feb, 1924, page 187, by Chas Mallory Williams. For a description of the case this article can be consulted. Under treatment with sodium thiosulphate there has been a marked improvement both in the skin and in the patients' general condition.

Below is the report of the arsenic findings. Thirty-one determinations for arsenic were made. The amounts found varied from zero to 0.626 mgs per 100 gmms of dried specimen or from none to more than twenty times the amount which could be considered normal.

No 2 J N, male, aged 34 years. Duration of the disease four years. Case showed extensive involvement of both ankles, left arm and fore-arm with the process extending down onto the dorsum of the left hand. The right thigh was involved and right inguinal region showed the typical pigmented condition.

Under treatment with sodium thiosulphate there has been improvement. There has not been any extension of the process in any of the involved areas.

Below will be found the arsenic findings in this case.

No 3 E S, female, Jewish, aged 9 years. Duration of the disease three years. The left inguinal region, fibular of the left leg extending onto the dorsum of the foot and the right costal region in the area supplied by the fifth dorsal nerve showed extensive involvement. The lumbar region was markedly pigmented. This patient has been under treatment since March 8, 1926. She shows considerable improvement both of the skin condition and of her general health. The pigmentation has practically disappeared and the infiltration is lessening.

The arsenic findings in this case were positive and at times showed as much as ten times the amount considered normal.

Below is the report of the different analyses.

No 4 F P, female, Jewish, aged three and a half years. Showed lesions on the scalp, neck, at the lower angle of the right scapular. On the lower left costal and left lumbar region there were two band like lesions which extended around onto the abdomen. These bands were about two inches wide. The left buttock showed a patch about three inches in diameter. The right thumb showed sclerodactylitis. The lesions were all markedly pigmented. The child was extremely fond of sweets and the mother admitted giving

**Psoriasis**—Two cases of this disease were examined for arsenical intoxication

The first was a male, aged 40 years, who had suffered from this condition for many years. When he applied for treatment the eruption was very widespread. The hands showed involvement of both the palms and the dorsa. The fingers showed the same condition. It was impossible for him to close the hands. The feet were in the same condition as the hands. In addition to the psoriasiform eruption on both the soles and palms there were a few keratoses. He was treated with injections of sodium thiosulphate every third day and on the alternate days the drug was given by mouth. He cleared up entirely except for a few typical psoriasis patches on the extensor surfaces of the large joints and on the back.

His urine showed the following amounts of arsenic 10-15-26, specific gravity, 1.022, total solids, 4.08, arsenic mg per 100 gms of dry specimen, 0.033

We might add that the only external treatment used was a mixture of wool fat and petrolatum.

The second case was a woman aged about 35 years who had shown the disease since childhood and in whom the condition had become generalized. The generalization had been present for many years.

Her urine showed the following

Date	Specific Gravity	Total Solids	Arsenic mgs. per 100 Gms. Dry Specimen
4/23/26	1.012	1.42	0.293
9/23/26	1.031	3.92	Trace

This patient did not continue treatment and her present condition is unknown to us.

In our former paper<sup>10</sup> we reported a series of patients in whom arsenic was an etiological factor in the causation of their eczema. The following cases are typical of what we are finding daily.

A. H., white, male, born in America, applied for treatment August 26, 1926, for a universal papulo-vesicular eczema associated with extreme oedema of the skin. The disease began in 1918 after he had been exposed to an insecticide containing arsenite of lead which was used to spray the wheat fields in his neighborhood. The Canadian Government had established a depot for the distribution of this preparation on his farm. About three weeks after exposure to this powder his eczema developed. He also showed severe dental infection.

A differential leucocyte count at the time of his admission to the hospital was as follows:

Polys	53 per cent
Lymphocytes	31 per cent
Transitionals	2 per cent.
Basophiles	1 per cent
Eosinophiles	12 per cent

Another count, made in October, showed 16 per cent eosinophiles and 24 per cent lymphocytes.

Case 2—Jos. H., aged about 35, white, was seen in September, 1926. He showed a universal erythematous oozing eczema. He was exposed to an insecticide several years before the development of his skin condition. In addition to his eczema he had a beginning subcapsular cataract in each eye. He responded to thiosulphate therapy and at present his skin condition is entirely normal. His eyes have recovered sufficiently for him to be able to read and write.

His arsenic findings were

Date	Specific Gravity	Total Solids	Arsenic mgs. per 100 Gms. Dry Specimen
9/18/26	1.020	3.53	0.042
9/20/26	1.020	2.46	0.066
9/22/26	1.026	4.45	0
9/24/26	1.021	3.99	Trace
9/26/26	1.030	5.91	0.305

Case 3—Mr. P. was referred from Cleveland, Ohio, recently for a squamous eczema of the hands of 14 years' duration.

Before the injection of thio his urine was negative for arsenic, after the first injection of 0.5 of this preparation his urine showed 0.404 mgs per 100 gms of dry specimen. After the second injection, given two days later, the amount of arsenic had risen to 1.119.

To report other cases would only be a repetition of the above.

## PIGMENTATION

Two cases of this condition were investigated. The first, a man aged 25 years, showed quite a large patch in the right iliac region with extension of the pigmented area around towards the back and down onto the thigh. In this case the clinical appearance corresponded to the typical text-book picture, a diffused discoloration with the hair follicles not involved but standing out as minute white specks on the dark brown background.

The second case was a woman, aged 30 years, with a uniform pigmentation over the left shoulder.

The arsenic findings in the first case were positive.

In the second case

	Date	Specific Gravity	Total Solids	Ars mgs per 100 Gms. Dry Sp. men

"	2/7/27	1.010	1.88	0.525

## ECZEMA

Our conception of the mechanism of this condition was discussed by us in a previous article<sup>9</sup>. At that time, it was pointed out that eczema was primarily a problem of oedema in which

		% Total solids	Arsenic in Mg per 100 Gm dry specimen

Arsenic poisoning causing motor nerve paralysis

I D, female, aged 22 years, was referred to us by the neurological department of the Brooklyn Jewish Hospital for motor ocular paralysis of the left eye. Examination at that hospital was negative except for this paralysis. The symptoms she complained of were ptosis of the lid and double vision.

She had partaken of food in which arsenic had been put with homicidal intent, later she suffered a severe mental and nervous shock (she and her escort were held up by a highwayman). Her treatment began December 1, 1926. At present she is entirely well.

Her arsenic findings were as follows:

	Date	Specific Grav	Total Solids	Mgs As per 100 Gms dry spec
Blood	12/1/26		20.68	0.104
Urine	12/1/26	1.018	3.24	0.255

## CASES ASSOCIATED WITH PIGMENTATION AND BLOOD VESSEL REACTION

Case No 1—S W, male, aged 25, Jewish, showed on the inner side of the left ankle pigmented, rounded, elevated lesions suggestive of hypertrophic lichen planus. The corresponding side of the right foot and ankle showed small pigmented lesions which were not elevated. Atrophy and moderate telangiectasia were present on each side. The biopsy report by Dr D S D Jessup was as follows:

Slight hyperkeratosis and acanthosis, flattening of the papillae. The papillary body and upper part of the derma showed a marked increase of capillaries between which there were many pigmented phagocytes. There was some pigmentation of the basal cell layer of the epidermis and scattered pigment, cellular and extra cellular all through the lower derma. The his-

tology of this case corresponds very closely to that of Majocchi's disease. Hyalin degeneration of the vessel walls was absent. The clinical appearance as stated above suggested lichen planus hypertrophicus, and the amount of pigment was greater than is usually seen in purpura annulata telangiectoides. The urine after thiosulphate showed 0.066 mgs of arsenic per 100 gms of dry specimen or twice the amount which could be considered normal.

**Leucoderma**—Two very unusual cases of this condition were seen. The first was a man aged 22 years, showed spots of depigmentation on the neck, shoulders and arms. These spots had been present for a few weeks when he consulted a physician who prescribed Fowler's solution. After he had taken this preparation for a short time there developed at the edges of the leucoderma areas a raised, elevated and scaly border, which showed moderate infiltration. On a few of the leucodermic spots themselves there was a fine telangiectasia. Case 2 was a female, aged 5 years, who showed an exact picture of the above case. In this case there was no history of medication. Thiosulphate of sodium was given by injection and her urine showed the following amounts of arsenic.

S W, Case 2 of leucoderma, described above.

Date	Specific Gravity	Total Solids	Arsenic mgs per 100 Gms Dry Specimen
11/2/26	1.033	4.57	0.056
11/12/26	1.028	4.38	0.191
11/19/26	1.022	4.16	0.142

Treatment with sodium thiosulphate has resulted in a complete disappearance of the inflammatory borders of the lesions. Of course, it has had no effect upon the leucoderma spots.

## ARSENIC IN ASSOCIATION WITH ARSENICAL MEDICATION FOR PEMPHIGUS

Mrs X, Jewish, aged about 55 years, had suffered for several years with pemphigus vulgaris. She had been treated by the Davis method with injections of iron cacodylate and coagulin. This line of treatment at first controlled the condition, but after a time it became inert, and when she was seen there were new lesions on the trunk and limbs, the old lesions would not heal, around and in the bases of the old bullae there was a large amount of pigmentation, in most of these places it was almost black and in some places, in addition to the pigmentation, there was a papillomatous growth. The patient complained of intense pruritus. The veins having become occluded by the arsenic injections, sodium thiosulphate was given by ingestion, 30 grains per day. The physician in charge of the case informed us a few weeks later that the pruritus was relieved, the pigmentation was absorbed, the old lesions healed and no new bullae appeared for some months.

part to dissolve and consequently to wash the offending substance away. This arsenic compound is insoluble in the tissue and blood fluids. When the hydrogen ion concentration is increased, the compound remains as a precipitate. Changes tending to reduce the hydrogen ion concentration cause the precipitate to go into solution. In the treatment of eczema and the nerve lesions with sodium thiosulphate, the excess of —SH radicals are able to dissolve the arsenic protein and facilitate its removal by the excretory organs.

### CONCLUSIONS

In this paper we have reported the following diseases and conditions in which arsenic was found in pathological amounts in the urine, eczema, scleroderma, leucoderma, psoriasis, Majocchi's disease, pemphigus, motor ocular paralysis and pigmentation.

In eczema we believe that it is present in at least 30 per cent of all the cases of this disease which we see. In some of these it seems to act as an exciting cause, the symptoms appearing almost at once after contact with the arsenic, as was shown in Case 1, at other times it seems to be deposited in the skin and to sensitize it and when later the patient is exposed to a banal irritant the reaction is in the form of eczema, this was shown in Case 2. It seems that in this delayed appearance of the eczema there is an explanation of Bloch's 5 per cent of seemingly normal persons who react as eczema on exposure to external irritants. It is also possible that other substances in addition to arsenic can be deposited in the skin in the same manner as arsenic is, these substances could be other metals such as mercury and lead or they could be proteins.

In scleroderma it seems that the arsenic attacks the vegetative nervous system first and later, possibly through this system, the endocrines are affected.

In the case of motor-ocular paralysis the arsenic had combined with the SH radical of the nerve tissue and through this combination the nerve function was altered.

In both the cases of motor nerve and autonomic nerve involvement, in all probability, there was a previous injury of some kind and this injury created a point of lowered resistance.

In the cases of leucoderma, which were unique, the affinity of arsenic for pigment caused the deposit in the pigmented region adjacent to the pigmented spots. Melanin contains sulphur and the arsenic in these cases, as in eczema, combined with the sulphur. Arsenic is also a direct vessel poison and this probably had an influence on the vessel dilatation which was present.

This same explanation in all probability applies to the case of pemphigus.

The findings in the cases of psoriasis would

seem to show that generalization in this disease is, in all probability, due to a retention of arsenic and not to an extension of the pathological process. In psoriasis of the palms the same is true. From our results in one of these cases we believe that all cases of these types should be investigated for arsenic intoxication and should be treated on the lines of arsenic elimination.

In the case resembling Majocchi's disease we were able to make too few determinations and the case was under observation too short a period to allow any conclusions.

Arsenic intoxication causing pathological conditions can be acquired either through medication, food contamination or through occupational contact. From our studies we believe that food contamination and occupational contact are the more frequent sources of the poisoning.

We believe that our studies are only the beginning of studies which will elucidate many obscure conditions.

the function of the cell itself was involved. Morphologically and histologically, even when studied in detail, eczema does not represent a sharply outlined picture, for there are found in it transitions to erythema, dermatitis and urticaria. The individual eczema stadia often appear co-ordinately, or are seen following each other. Its pathology, briefly summed up, is an oedema of the skin most marked in the epidermis and the upper part of the derma and preceding this oedema an engorgement of the vessels of the papillary and, at times, of the deeper layers of the corium. It is distinctly an inflammatory condition involving the blood-vessels and epithelial cells associated with oedema. It is not necessary to repeat the different theories about the causation of eczema. Bloch's findings (quoted from Pulay), however, show that the skin of 5 per cent of seemingly normal persons was hypersusceptible to ordinary irritants. In a previous paper, we gave our findings on arsenical causation of eczema<sup>10</sup>. Since the publication of that article, we have had numerous cases in which the arsenic findings and the resolution of the diseased process under arsenic eliminating treatment has completely borne out our previous conclusions and at present it seems that in not less than 30 per cent of all cases diagnosed as eczema, arsenic is either the actual exciting cause or at least a contributory cause of the greatest importance.

#### MECHANISM OF THE ACTION OF ARSENIC

The investigations of Mueller and others<sup>11</sup> have shown that following the injection of the arsphenamines, there is a reaction of the involuntary nervous system immediately in both the healthy and in the syphilitic. Fordyce and others<sup>12</sup> have shown that, following these injections, the arsenic disappears rapidly from the circulation and that as the amount of arsenic excreted is not equal to that lost from the blood stream it must be deposited in the tissues. The excretion of arsenic takes place by way of the kidneys, liver and, in cases of dermatitis, through the skin also. After the primary drop the amount of metalloid increases from the 72nd to the 96th hour after the injection. It then maintains a fairly constant level of 1 mg of arsenic per 100 gm of dried specimen. This constant elimination shows that the arsenic is being liberated from its storage places in the body into the blood stream and will be passed from the blood to all parts of the body, one part going to the excretory organs and the other part accumulating in the tissues. In the normal being this process continues until practically all the arsenic is eliminated. Mueller and Myers have shown that the reaction of the vegetative nervous system is greater when it is out of balance, especially when there is a predominance of the vagus component. The autonomic ner-

vous system controls excretion, the calibre of the blood vessels, electrolyte balance, the detoxicating function of the liver and, through the endocrines especially the thyroid, water metabolism of the tissues.

In disturbances of the vasomotor nerves by a prolonged circulation of arsenic in the blood over a protracted period of time, three principal excretory organs, the liver, skin and spleen, lose their power not only of excreting arsenic from the body but also of transferring arsenic and probably other products of metabolism from their tissues to the circulation.

From the chemical analysis of the scales, the arsenic protein has been proven to be a chemical combination with cysteine, the arsenic combining with the SH radical of that protein, which is found in the cytoplasm of the cells. The cell nuclei contain glutathione which also has a —SH radical and nerve cells also contain this same —SH group.

#### ACTION IN ECZEMA

Eczema which is an inflammatory reaction shows, as do all such reactions, vessel dilation and increased cell permeability for the blood plasma and consequently an inflammatory oedema develops. This vessel dilatation can be caused directly by a primary vessel disturbance or through the action on the vessel endothelium and walls or indirectly through the nervous system. Involvement of the vegetative nerves is present in all oedemas. Inflammation-producing substances are divided according to their point of attack into two classes. First, those which act through the nervous system and, second, those which act directly as a specific vessel poison or as protoplasmic poison destroying or altering the living protoplasm. Arsenic is a vessel poison causing vessel dilatation. Wells<sup>13</sup> states that the combination of a foreign protein or a chemical with the body proteins gives them antigenic properties. In oedema there is always an alteration of electrolytic balance. In eczema, therefore, we find the following changes caused by arsenic. A primary disturbance of the vagus-sympathetic balance. The findings of eosinophilia as seen in the case of A. H. would point to a vagotonia. The frequent development of symptoms of vagotonia during treatment with sodium thiosulphate and the beneficial effects of calcium therapy at this time are added support of this hypothesis. The perverted carbohydrate and chloride metabolism as shown by us<sup>11</sup>, shows the action of arsenic either directly on the liver or reflexly through the vegetative system, or what is more probable, a combination of both. The arsenic combination with the protein of the cells of the skin and other organs alters electrolytic balance. The action of all living tissues is to try to get rid of foreign bodies. In order to do this, more fluid is brought to the

ence of concurrent conditions. Headache, otherwise unexplained, has been a rare complaint. Some observers have reported emotional irritability, and impaired imagination, giving rise to weird tales and impossible explanations, but I frankly confess that I have had no experience in this field.

Examination of the heart usually shows a somewhat rapid rate, especially on slight exertion, and varying markedly with the mental state. The heart seems to "flap" against the chest wall, as though in a lazy, shortened effort at contraction. Frequent extra systoles are found without other explanation than the evident fatigue. There is often a rapid change of color, particularly noticeable with varying mental states of anger, fear, or surprise.

A rather frequent complaint is that of excessive perspiration of the neck, axillae, palms and feet. This often accompanies the finding of cold, bluish, or mottled, clammy extremities. The hair and nails are often brittle. Itching and the habit of scratching are frequent, although no sign of rash or other possible cause can be demonstrated. "Black and blue" marks appear easily, with only slight provocation, or with no known trauma.

Fatigue kiddies have frequent "colds," or manifestations of mild allergy—mild hay fever, or mild asthmatic bronchitis. There is a frequent clearing of the throat without demonstrable reason, and often unknown to the patient himself. Sighing is common, often with a cogwheel type of inspiration resembling sobbing.

The mucous membranes of the mouth are apt to show very little if any change, other than the finding of swollen, spongy gums, which bleed easily, but which do not necessarily give evidence of infection. Parents often take exception to the appearance of the gums because of an extra effort put forth to keep the mouth in excellent shape. There is often an accumulation of gas throughout the stomach and intestine, and an almost constant finding of an abnormally large amount of gas, accompanies the relaxation of the abdominal wall. Constipation appears to be the rule, often without change in the type or character of the stool. I am tempted to believe that, in certain cases, at least, retention of stool arises from a failure to appreciate a desire to have an evacuation, or from difficulty in relaxing the sphincter.

Mothers often complain that the patient urinates frequently during both the day and night, but distension appears to waken him before involuntary voiding takes place. In other words, enuresis is not frequent, except when a marked exhaustion is present, and when the sensibilities may be markedly dulled. There is rather frequent irritability of the genitals—erections on slight irritation, as from clothing, are frequently complained of.

Both mental and physical endurance appears to be lowered by fatigue. It seems particularly

marked in its relation to infections, and in these histories, it is frequently noted that a child is discovered to be the victim of several illnesses only since the onset of symptoms referable to fatigue. We frequently hear that a child has managed to escape infections until some definite fatiguing effect was noted. Granting that school routine brings undue contact with disease sources, have we forgotten that the average child becomes as tired with his duties as his mother at her task, and his father in his work, or possibly, as his doctor in his sphere of activity?

Another observation is that convalescence from infectious diseases appears to be delayed where the patient has been depleted by a degree of fatigue over some time. In a general way it may be said that the more tired an individual, the longer it takes him to react from a given illness.

I wish it were possible to crystallize into concrete form certain factors which may be regarded as causative, as follows:

- 1 Effort beyond the individual child's ability,
- 2 Lack of balance between mental and physical capacity, as for example, the child who finds it impossible to work or to talk as rapidly as he thinks, the "high voltage" child,
- 3 Attempting to keep up with older, stronger, or larger members of the family or school,
- 4 The constant association with adults, or association with adults over a long period of time, where the mental and physical reaction is copied after the example of the adult. This is especially marked in the all too frequent attempt on the part of adults to place responsibility upon the child,
- 5 Urging along in school, skipping grades, attempt to keep up to a reputation, individual or family, for brilliance,
- 6 Studies outside of school—music, especially with long practice hours, dancing lessons,
- 7 Overplanned routine for children, in which there is no time to sit down, or insufficient time for sleep, meals, et cetera. This is best illustrated in the governess problem, wherein a child has practically no time for spontaneous diversion. Another example is that of visitors in the home, where a youngster attempts to do the entertaining, and often tires out several adults in any given day,
- 8 Daylight saving time, often regarded as an extra hour for vigorous and fatigue-producing activity,
- 9 Unsupervised athletics or playground,
- 10 Overclothed—where the garments are so many or so poorly arranged as to make for a large amount of weight to be carried, or else make it impossible to move freely,
- 11 Eyestrain,
- 12 Poorly ventilated rooms, especially bedrooms, faulty posture in bed, too heavy bed clothing, habit of covering the head in sleeping,
- 13 Overeating or improper eating, wherein too

## FATIGUE IN CHILDREN\*

By GEORGE R IRVING, M D, NEW YORK, N Y.

**A**TENTION has been attracted to the problem of fatigue in children because of a relatively large number of children concerning whom the chief complaint has been "being tired." In addition, there are certain children who, ill with diverse conditions, usually show marked improvement only when adequate rest is secured. There is also the occasional child who presents a set of vague and indefinite signs and symptoms which do not fall into usually accepted channels, and who exhibit their evidences of illness without definite accompanying pathology.

A differentiation must soon be made between the ordinarily accepted fatigue process as part of the normal body routine, and that degree of "over-fatigue" from which complete recovery is not immediately possible, and which, by repetition, may lead in a cumulative way, to more serious difficulty. The term "overfatigue" is a faulty one, in that all fatigue implies a condition of being tired, but is generally accepted to mean a much greater degree of tiredness, often approaching exhaustion. There are no hard and fast lines where fatigue begins, nor where the varying degrees of fatigue may be separated, nor is it possible to completely isolate this condition from the many diseases occurring at the same time. In other words, it must be readily admitted that one is not dealing with a sharply defined disease entity, but rather with one having wide and frequently changing limits. It is most difficult to separate fatigue from a large group of intestinal disorders and the errors of elimination. Fatigue, then, may be merely a symptom, occasionally a disease process in itself, but particularly an abnormal process predisposing to some more serious disorder. With the exception of a fairly well defined "acute fatigue," the onset is nearly always insidious, stretched over a relatively long period of time, and may be entirely overlooked until some intercurrent malady attracts attention.

One who has dealt with many children may easily draw the picture of the "tired child," who seems always to be making an effort to pay attention, always "on edge," or easily annoyed. His speech is often hesitant, as though "shy", sometimes there is the attempt to speak too rapidly, may be in a strained tone, and with more or less stammering. His color is nearly always pale, frequently with little tell-tale spots of high color—a peculiar type of flush upon the otherwise greyish or pallid skin, most often located near the eyes. The posture is very frequently defective, nearly always drooping, and often tensely held in whatever position is assumed. There is nearly always a forward bowing of the shoulders, a relaxation of the spine, particularly that backward bowing

in the lumbar and lower dorsal region when sitting or, on standing an exaggeration of the normal curve, with marked thrusting backward of the shoulder blades. This flattens the upper anterior thorax, and helps protrude the abdomen, particularly in the flanks. The position of the head is thrown forward at the chin, and the expression of apparent inattention, or extreme effort in concentrating, are very characteristic. Lines of facial expression seem often to be obliterated by some subcutaneous thickening, or trick of muscle tenseness, leading for example, to tightly drawn, frequently cracked lips, varied by little spasms of the facial muscles. The eyes appear partly open, with rather red edged lids, deep circles underneath, and with muddy colored sclerae, approaching a shade of icterus. In certain states of fatigue, the impression is given that the eyes are making an effort to see everything going on, wherever the child happens to be, and no matter how many persons or things may be in his vicinity. The extremities may be in almost constant motion, or displaying frequently repeated movements suggesting chorea, ankles are nearly always relaxed, with feet diverging, suggesting uncomfortable arches. The general picture of a weary child is one never to be forgotten.

As part of a process of this type, many signs and symptoms are to be observed, and in this connection, many of those most frequently found are here enumerated. Owing to the fact that the nervous system appears to be a frequent sufferer, I would mention irritability as one of the most common. With a general hypersensitiveness, often varying with the time of day, et cetera, this irritability may show itself by a quite uncalled for "flood of tears," a brain storm or "tantrum," a keen dissatisfaction with things which usually please, a difficulty in getting along with other children or with strangers, or an inability to accept slightly different conditions. There are frequently tricks of vision, culminating in the complaint of inability to see distinctly, and yet for which the oculist may find it impossible to prescribe lenses. Teachers frequently report that a student does not pay sufficient attention to understand what is going on, or merely dismiss the condition with the proverbial "poor marks." There is frequent inability to relax, often going to such an extreme as to result in the observation that "he fights sleep." When sleep is attained it is apt to be restless, and the child may awaken, cross and irritable, and claim an inability to find a comfortable position. He may show a marked susceptibility to slight changes of temperature, with teeth chattering and body shaking in a chill on a few degrees drop, or perspiring freely with a relatively slight rise. The reflexes are variable, depending upon the degree of fatigue and the pres-

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Niagara Falls, N Y, May 10, 1927

attendant can be doing best work without paying direct attention to the patient, and at the same time can accomplish things in the way of mending, sewing, or reading quietly to herself. At times a patient is to be read to, pictures explained, and quiet conversation carried on, but these contacts will have to be gauged by the underlying cause of the process, and by the patient's reaction to that which is talked about. The child must accept the plan of his nurse or supervisor as a decision of the highest court, whereby certain problems are quietly dismissed, the mind diverted, and non-stimulating conversation substituted as needed. A simple plan is to have the patient read to, under certain hard and fast conditions, as in a darkened room, with a bandage lightly over the eyes, the body slightly propped up on pillows, at the same time that the patient is taught to breathe slowly and deeply, and keep his extremities perfectly relaxed. It is a good plan in reading to resort to only those stories of a non-stimulating nature, which have been previously read and reread. Rewards for co-operation are of some value, but it must be distinctly understood that such possible rewards are not to be discussed with the patient, nor is the bribery or the threat of withdrawal of reward to be countenanced. Have it clearly understood that if some unusual strain is to come, the patient should prepare for this in advance, instead of agreeing to make up for it at a later time. In this way a child sleeps an extra hour in the morning in preparation for sitting up out of bed twenty minutes in the afternoon, instead of waiting until after the sitting up session with the expectation of his sleeping an extra hour that evening. This plan of securing rest might be applied in many fields.

The prophylaxis of the fatigue condition is largely a matter of education on the part of parent, medical advisor, governess, teacher, ath-

letic supervisor, or whoever comes in contact with the child. The adult contact should be a good observer of a child's individual peculiarities, his ability to execute an effort, his reserve power, et cetera, in addition to being well informed as to what the average child should attempt and can easily accomplish. Most children have little judgment as to what they can stand, and no judgment as to what they can do under varying circumstances. It may be safely said that certain methods of approaching children should be avoided: too long an argument, nagging, undue fault finding, irritability on the part of parent or teacher, hasty resort to drastic methods of discipline. The adult in the case should always be fair, and should upon all occasions teach, and be an example of, moderation. Remember the part played in the vicious circle of affairs, when certain effort causes fatigue, which may be added to by overeating or eating, still further intensified by restless sleep or travel, only to find the child becomes more and more tired, and consequently less able to control his sundry and diverse processes. It is to be remembered that certain types of diet are stimulating, certain contacts, adults or playmates, may tend to over-excitement, and some forms of activity or amusement may so overwhelm a child as to lead to a very marked condition of fatigue, particularly if repeated.

This leads to the point of a frequent checking up of the physical condition, a careful going over of the bodily proportions, possible physical handicaps, the special senses, possible idiosyncrasies, and gives a certain amount of information as to what one's tolerance may be. Furthermore, the early recognition of the evidences of fatigue may prevent the incidence of a more serious degree of this condition and may lessen the child's opportunity to be the victim of nutritional and infectious maladies.

## ULCERATIVE AND GANGRENOUS BALANITIS\*

By MATTHEW A. REASONER, B.S., M.D., F.A.C.S.

Lieut. Col. Med. Corps, U. S. Army, Brooklyn, N. Y.

VINCENT'S spirochete most often infects the mouth and throat but it is by no means limited to these areas. Venereal and genital infections are rather common in countries and with peoples where the conditions are such as to favor the spread of the disease. These predisposing conditions are over-crowding, uncleanness and scanty use of soap. The disease is doubtless spread by direct contact and perhaps to a limited extent by indirect methods, as with drink-

ing cups. As ulceromembraneous angina, it was very prevalent among the American and British soldiers during the World War and thus, doubtless, because the infection is so common among the peasants with whom they came into contact and those who first became infected served to infect others.

When our soldiers arrived in the Rhineland they had plenty of time and opportunity to clean up and wash, to take frequent baths and use their tooth brushes properly and if they so desired, to avoid such intimate contact with the peasants and each other as had been necessary while in France.

large a quantity or too indigestible a type of food is taken in, especially after vigorous play. Fatigue seems to become much more marked when digestion is attempted in the presence of even a slight degree of tiredness,

14 Localized discomfort, as nasal obstruction, or slightly loosened teeth,

15 The group of children known as "trouble borrowers" or "anticipators," who have become accustomed to looking forward to something unpleasant. This group also includes the children who have been constantly "nagged" in order to discipline them, or in the effort to make them pay attention.

The pathology of this condition is nearly always complicated by that of other intercurrent illnesses. It resolves itself into the findings as the result of life processes, only in exaggerated form. There is little to work upon, as there is limited material for examination, particularly under the present conditions of physiological chemistry and other methods of approach. There is probably a high degree of intoxication resulting from failure of elimination, improper, slow nutrition and complicated by the intoxications of probable disease processes.

The prognosis, uncomplicated, is nearly always good, although slow. In general, the longer the duration of fatigue, the slower the recovery. Individual reaction to the cause and the relief of complicating factors play an important part. Intercurrent conditions, such as those of twentieth century life, the need of an education, certain infectious diseases, and the wear and tear of competition, even in childhood, stresses the large degree of co-operation required from all directly, or indirectly, concerned. Another important factor lies in the ability of the patient to adjust himself to conditions, when he becomes improved. There is a marked tendency to recurrence, although recurrence does not necessarily result from the same causative factor.

Treatment must be directed at the particular cause or set of causative factors at the bottom of the process—easy in theory, often most difficult in the practical workout. Mechanical rest means not a mere going to bed, but a complete relaxation, both mental and physical, and over a relatively long period of time. It is questionable whether a real rest can be attained in less than three consecutive days, and this may have to be stretched out over a period of weeks. As soon as the initial rest is obtained, more and more leeway may be allowed, permitting partial resumption of play, or school, and some association with other people. It is important, that in combatting fatigue, few people and only those with a quiet manner, have access to the patient, so essential is the power of example. Avoid all argument with the patient. Occasional explanations, brief warning of what is to be undertaken, and answering of some essential questions is necessary, but

to carry on a long conversation or to attempt a complete conversion to a way of thinking is practically impossible, and not productive of results. If necessary to attain the end, secure a definite geographical change, as, from city to country, from seashore to mountains, or from sea level to hills, or the reverse, as indicated. Another important point about securing the necessary rest, is to establish an absolute regularity of the day's routine, without the patient being aware that a new regime has been instituted, and without the patient being consulted about it.

Sedative baths, usually warm, and frequent cleansing of the skin, usually help. As soon as practicable, the institution of mild corrective exercises, never to the point of mental or physical exhaustion, may be used to occupy the patient's time, and also to begin the upbuilding process. Secure all the direct sunshine that is possible providing this is not irritating, and whenever possible, suggest that all activity be carried on in the open air. A frequently helpful measure is the relief of cold extremities by the use of gentle friction, electric pad, or hot water bottle, or the wearing of bed socks. Gentle massage over large areas with stroking and rubbing is often very grateful, and distinctly helpful in assisting elimination.

I have been unable to completely separate the fatigue problem from that of insufficient elimination. However, the elimination factor is an extremely important one, in connection with fatigue from whatever cause. Forcing water, care of the skin, and the institution of deep breathing exercises to assist lung action are important. The light laxatives, preferably the saline, are indicated early, while later, bowel control by mechanical or dietetic means may be sufficient. A series of saline laxatives may be rotated, but the main thing is to secure evacuation.

The sedative is found to be a legitimate medicinal treatment, providing it does not interfere with some other phase of treatment, as for instance, bowel action. Morphine derivatives are to be avoided, but bromide preparations, or the less harmful of the coal tar products will not only be found advantageous, but distinctly beneficial in securing rest, and in taking the edge off the unusual things which crop out now and then in the followup. Another valuable point to be remembered, is the mental effect of the use of medicine being explained to the child patient,—he has no judgment in the matter and should not be consulted.

It is difficult to estimate the value of suggestion and mental therapy under conditions of fatigue. If the treatment can be turned into a game, and relaxation obtained with as great interest as was manifested in the thing which brought on the fatigue, you will have no difficulty in this phase of the treatment. The example of quiet surroundings, and a quiet personality in the room, play a very important part here. The nurse or

attendant can be doing best work without paying direct attention to the patient, and at the same time can accomplish things in the way of mending, sewing, or reading quietly to herself. At times a patient is to be read to, pictures explained, and quiet conversation carried on, but these contacts will have to be gauged by the underlying cause of the process, and by the patient's reaction to that which is talked about. The child must accept the plan of his nurse or supervisor as a decision of the highest court, whereby certain problems are quietly dismissed, the mind diverted, and non-stimulating conversation substituted as needed. A simple plan is to have the patient read to, under certain hard and fast conditions, as in a darkened room, with a bandage lightly over the eyes, the body slightly propped up on pillows, at the same time that the patient is taught to breathe slowly and deeply, and keep his extremities perfectly relaxed. It is a good plan in reading to resort to only those stories of a non-stimulating nature, which have been previously read and reread. Rewards for co-operation are of some value, but it must be distinctly understood that such possible rewards are not to be discussed with the patient, nor is the bribery or the threat of withdrawal of reward to be countenanced. Have it clearly understood that if some unusual strain is to come, the patient should prepare for this in advance, instead of agreeing to make up for it at a later time. In this way a child sleeps an extra hour in the morning in preparation for sitting up out of bed twenty minutes in the afternoon, instead of waiting until after the sitting up session with the expectation of his sleeping an extra hour that evening. This plan of securing rest might be applied in many fields.

The prophylaxis of the fatigue condition is largely a matter of education on the part of parent, medical advisor, governess, teacher, ath-

letic supervisor, or whoever comes in contact with the child. The adult contact should be a good observer of a child's individual peculiarities, his ability to execute an effort, his reserve power, et cetera, in addition to being well informed as to what the average child should attempt and can easily accomplish. Most children have little judgment as to what they can stand, and no judgment as to what they can do under varying circumstances. It may be safely said that certain methods of approaching children should be avoided too long an argument, nagging; undue fault finding, irritability on the part of parent or teacher, hasty resort to drastic methods of discipline. The adult in the case should always be fair, and should upon all occasions teach, and be an example of, moderation. Remember the part played in the vicious circle of affairs, when certain effort causes fatigue, which may be added to by overeating or eating, still further intensified by restless sleep or travel, only to find the child becomes more and more tired, and consequently less able to control his sundry and diverse processes. It is to be remembered that certain types of diet are stimulating, certain contacts, adults or playmates, may tend to over-excitement, and some forms of activity or amusement may so overwhelm a child as to lead to a very marked condition of fatigue, particularly if repeated.

This leads to the point of a frequent checking up of the physical condition, a careful going over of the bodily proportions, possible physical handicaps, the special senses, possible idiosyncrasies, and gives a certain amount of information as to what one's tolerance may be. Furthermore, the early recognition of the evidences of fatigue may prevent the incidence of a more serious degree of this condition and may lessen the child's opportunity to be the victim of nutritional and infectious maladies.

## ULCERATIVE AND GANGRENOUS BALANITIS\*

By MATTHEW A. REASONER, B.S., M.D., F.A.C.S.

Lieut. Col. Med. Corps, U. S. Army, Brooklyn, N. Y.

VINCENT'S spirochete most often infects the mouth and throat but it is by no means limited to these areas. Venereal and genital infections are rather common in countries and with peoples where the conditions are such as to favor the spread of the disease. These predisposing conditions are over-crowding, uncleanness and scanty use of soap. The disease is doubtless spread by direct contact and perhaps to a limited extent by indirect methods, as with drink-

ing cups. As ulceromembraneous angina, it was very prevalent among the American and British soldiers during the World War and this, doubtless, because the infection is so common among the peasants with whom they came into contact and those who first became infected served to infect others.

When our soldiers arrived in the Rhineland they had plenty of time and opportunity to clean up and wash, to take frequent baths and use their tooth brushes properly and if they so desired, to avoid such intimate contact with the peasants and each other as had been necessary while in France.

\*Published with permission of the Surgeon General U. S. Army who is not responsible for any opinion expressed or conclusions reached herein.

Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, May 11, 1927.

There followed a marked improvement in conditions but nevertheless until the very last, there was always a number on sick report suffering from infections with Vincent's spirochete. It was an impossible matter to get the entire command cleaned up, and meanwhile there was the usual irresponsible element continually acquiring new infections.

It is generally believed that the spirochete which is named after Vincent, its discoverer, is the cause of the injury done in the disease. Vincent made his original study on hospital gangrene and found the organisms present to be the same which are often found in the mouth and throat. There is usually with the spirochete a fusiform bacillus and there is probably some relationship between them though this is not admitted by so good an authority as Krumwiede. As has been so beautifully shown by Tunncliffe<sup>1</sup> there are always three zones which can be demonstrated in a cross section of an active lesion. The deepest or advancing zone contains spirochetes but no fusiform bacilli, the intermediate zone contains spirochetes and a certain number of fusiform bacilli and the superficial or covering membrane, contains many spirochetes, fusiform bacilli and other organisms. The spirochete may also be found in the apparently normal mouth as a chronic infection, in which case it inhabits the crypts of the tonsils and the gum just beneath the border surrounding the teeth.

The spirochete is freely motile, somewhat irregular and loosely coiled. It is from 10 to 30 microns in length and about 0.5 microns in diameter and has usually from three to six turns. It grows anaerobically and produces a disagreeable odor. It stains readily with Giensa's and Wright's stains and is Gram negative. The bacilli are straight or slightly curved rods which taper at the ends to sharp or blunt points. The bacillus stains with all the common stains and is Gram positive.

In 1916<sup>2</sup> a report was made upon the marked spirocheticidal effect of soap solutions upon *Treponema pallidum*. It was found that a 0.1 per cent of the ordinary toilet soaps, when floated under the cover glass of a slide of *Treponema pallidum* undergoing examination, caused their immediate death and dissolution. The same effect was produced with *Treponema pertense*, of yaws, which is an organism so similar to that of syphilis that it cannot be differentiated by any known method of microscopic examination or staining reaction. During the years 1921 and 1922 in the laboratory in connection with the Station Hospital in Coblenz, Germany, relatively large numbers of Vincent's infections were being examined daily and with this quantity of material available it was an easy matter to determine the effect of this same procedure upon Vincent's spirochete. This was accomplished in several ways. When soap solutions were introduced into

the slide undergoing examination, the result was similar to that observed with the spirochete of syphilis and yaws, except that the spirochete of Vincent is somewhat more resistant. Mouth and throat lesions were treated by swabbing with relatively concentrated solutions of soap, and this was followed by gargles of diluted solutions. The effect was either to cause a temporary disappearance of the surface spirochetes and fusiform bacilli or to lessen their number. A series of twenty-five patients was treated entirely in this manner and all of them cleared up in only a little more than the average time required by the usual methods of treatment.<sup>3</sup> Genital lesions treated with soap solutions showed the same results observed in infections of the throat and gums.

It was observed that the incidence of all Vincent's infections was for the most part among those in whom it was apparent little attention was paid to personal hygiene and the cleanliness of the body. There was little of this disease among the officers and the better class of non-commissioned officers and privates. It was an obvious deduction that in a general way the incidence of these infections varied inversely with the amount of soap and tooth pastes used and their personal contact with the infected inhabitants. Most tooth pastes including those made in Germany have a small percentage of soap in them and it would appear that it is the element which is of the greatest value in the prophylaxis of mouth infections. The German physicians informed me that these infections were most common among the inhabitants who lived in close quarters and under insanitary conditions. Corbus<sup>4</sup> in speaking of genital infections stated that these were rare in his private practice but relatively common in his dispensary work. I think that the evidence is quite clear and convincing that soap and cleanliness and proper living serve as a means of prophylaxis against such infections.

While the term "venereal" is often used in describing genital lesions, yet I do not believe that this is true in the same percentage which exist with gonorrhoea and syphilis. I would expect a high percentage but not necessarily 100 per cent. There is no reason why the organisms might not be transferred from the mouth to the genitalia by means of the hands and if the conditions there are favorable there is no reason why they should not continue to grow and do damage. When there is a marked phimosis or redundant prepuce, this results in an ideal field for the development and growth of the spirochetes. There is bodily warmth, moisture, a moist mucous membrane and sufficient lack of oxygen for this anaerobic organism. It would appear that such conditions are at least as favorable as in the mouth but infection is less likely.

Bataille and Berdel<sup>5</sup> first described this disease as a clinical entity.

Corbus and Harris<sup>6</sup> were the first in this country to describe the infection

The chapter by Corbus in Cabot's Urology is the most comprehensive of any I have seen. Scherber and Muller<sup>7</sup> reported fifty cases which they observed in Fenger's Clinic. Scherber<sup>8</sup> reported 81 infections seen in the same clinic during the course of four years.

Some interesting observations were reported by Brams, David and Pilot.<sup>9</sup> They examined 100 men but did not give data as to the length of foreskins and degree of phimosis further than to state that those having a redundant foreskin showed the greater percentage of infections. In these 100 men they found *Sp. Vincenti* and *B. fusiformis* present in 51, or 51 per cent. This is much higher than the results secured by me in Germany where these organisms are more prevalent. It is true that my examinations were made only on those having some sort of a genital lesion but it is not believed that this should make any difference in so far as a reduction is concerned. In the examination of 708 individuals having genital lesions, the spirochete of Vincent was found in the lesions of only 49 individuals. Spirochetes of various kinds were found in others but they did not in my opinion have the characteristics of *Sp. Vincenti*. Brams, David and Pilot found the fusiform bacillus always present with the spirochete. It was usually present in smaller numbers and appeared as a straight or slightly curved rod tapering into sharp or blunt ends. The spirochetes were often present in large numbers. In the presence of a long phimotic prepuce, there were usually many cocci and short bacilli. They also found the following organisms in the proportions stated:

Staphylococcus albus and aureus	90%
Streptococci	17%
Diphtheroid organisms	50%
<i>B. coli</i>	3%

The same investigators also examined 24 pregnant women and in 17 of them or 58 per cent found *Sp. Vincenti* and *B. fusiformis* present around the clitoris.

McConnell<sup>10</sup> reported a case of Vincent's involvement of the cervix with characteristic lesions. Robinson<sup>11</sup> reported a puerperal and post-puerperal infection characterized by a number of small superficial ulcers about the genitalia. Capt. Wm. D. Gill will report later upon two cases of erosive cervicitis seen in Coblenz in which the characteristic spirochetes were found. There was conducted in Coblenz, Germany a hospital for diseased prostitutes. During the period in which this hospital operated there was a total of 2,249 admissions. Dr. Kurt Roscher, the physician in charge, was possessed of the necessary knowledge and experience to fit him most admirably for the position. He has stated to me in a personal communication<sup>12</sup> that he has never seen the charac-

teristic ulcerative or gangrenous types of this disease in a female. Dr. Herman Feit, now of New York City, but who has had a rather broad experience in the Rhineland, has informed me that his experience is similar to that of Dr. Roscher. These women were practically all living under worse sanitary conditions than the soldiers and it was from them that the most of the venereal infections among the soldiers were contracted. It would appear that the active or acute manifestations of this disease do not often appear in or on the genitalia of the female. They may and do carry the infection but it is rarely manifested by pathological lesions.

The spirochete of Vincent is a versatile organism as it may appear under a variety of conditions. The following diseases may be caused by it: Vincent's angina, acute ulceromembranous gingivitis, noma, hospital gangrene, pyorrhoea alveolaris, putrid pneumonia, otitis media and acute and gangrenous balanitis. In some conditions the spirochete invades the blood stream and has been isolated therefrom.

One can do no better than adopt the definition of Corbus, which is as follows: "Erosive or gangrenous balanitis is a specific venereal disease caused by a symbiosis of a vibrio and a spirillum, with local and constitutional effects varying with the severity of the infection." The incubation period is from five to seven days. It is noticeable that the infection may be so slight as to cause but little annoyance and it is most often of this grade of severity. In such case there is only a localized destruction of the epithelium, after which there appear superficial erosions which are usually multiple. The erosions require about eighteen hours to develop. They are found in the preputial sac and most often in the sulcus coronarius and are accompanied by moderate burning and itching, and the presence of a small amount of bad smelling pus. The dorsal lymph vessels become palpable and there is always a degree of glandular enlargement. This must be borne in mind because a sore on the penis accompanied with glandular enlargement and spirochetes in the discharge is not necessarily syphilitic. In slight cases there is no marked pain and constitutional manifestations are lacking.

If there is enough phimosis to make conditions favorable the entire surface of the sulcus may be involved. It is largely a question of how badly the patient needs circumcision and once he becomes infected in this manner he needs it much more than previously. The infection may not get so far back as the sulcus and in cases where the prepuce is not adherent or there is no real phimosis, healing may take place without treatment. If the phimosis is marked, and especially if the organ has not been kept in a cleanly condition, it is probable that the disease will be evidenced by ulcerations following the erosions. These ulcers become a bright red and are surrounded by a whitish mem-

brane similar to that which first covered the erosions. Later they may assume a punched out appearance and become irregular and multiple and have a well marked red border. There is a considerable discharge of a thin odorous pus. With a severe involvement, the temperature may rise to 103 degrees and be accompanied by malaise, chills, fever and vomiting. The deeper the ulcers, the greater will be the discharge and the worse the odor. In such case there will be considerable edema manifest in the prepuce, sufficient to prevent retraction. There will be itching, burning and tenderness but not much severe pain.

In the severe type where the involvement becomes gangrenous in character, there is of course a considerable degree of venous stasis with marked exudation. This may appear within 2 or 3 days after the first erosions. As a result of this condition the phimosis naturally increases and this produces a more marked anaerobic condition which favors the growth of this anaerobic spirochete. By this time the spirochetes have invaded the deeper tissues and the defensive agencies of the body have become less able to resist and gangrene supervenes. Constitutional symptoms are present and there is a marked odor and an offensive discharge. In all cases the pus is of course contagious.

Involvement of the throat may exist as a chronic condition with exacerbation from time to time without obvious reason therefor. The same condition may exist with genital infections. It is well established that general and constitutional diseases, such as bronchitis, pneumonia, the exanthematous fevers, diabetes and nephritis predispose to acute mouth infections. While this may be true as regards acute erosive and gangrenous balanitis, the writer has never observed it.

The examinations upon which this paper is based extended over a period of about two years and were performed upon 708 hospital admissions, all of them having some lesion suspected of being venereal in character. The list shows a total of 49 acute infections with Vincent's spirochete and of this number, 10 had a coincident initial lesion of syphilis.

#### CLASSIFICATION OF INFECTIONS

Spirochetes found with only slight erosions	5
None of the five had a phimosis or voluminous prepuce	
Three had venereal warts	
Slight erosions, no ulcerations, slight discharge	4
No one of the four had what might be termed a phimosis	
Ulcerations with a moderate amount of discharge	9
Lesions in sulcus, prepuce of moderate length	3
Lesions in sulcus and on glans, prepuce of moderate length	6
In one of the six, discharge was sufficiently marked to cause a tentative diagnosis of gonorrhoea.	
Ulcerative type with marked discharge and redundant prepuce	20

Swollen prepuce, unable to retract	15
Three with tentative diagnosis of gonorrhoea	
Prepuce could be retracted, milder in type	5
Lesions only in sulcus	1
Lesions in sulcus, on glans and internal prepuce	3
Three had also marked involvement of gums or tonsils	

#### Gangrenous type

Observed on the first day of the beginning gangrenous process. This patient had been under treatment for syphilis and had had a moderately severe salvarsan reaction. For this reason it was thought best to attempt treatment by other measures. At the end of two days it was realized that this was not sufficient and he was given an intravenous injection of salvarsan with the result that the progress of the disease was terminated. There was a loss of a portion of the glans but otherwise no serious harm was done.

Double infection, chancre and erosive and gangrenous balanitis	10
Moderate foreskin, induration, no characteristic balanitis	4
Moderate foreskin, induration and erosive balanitis	1
Redundant prepuce, only slight erosions in sulcus	2
Redundant prepuce, chancre and characteristic balanitis	3
In 3 of the 10, the diagnosis of syphilis was made at a later date.	
Total	49

It will be noted in the summary of the above case histories, considerable attention has been paid to the condition of the prepuce and the presence or absence of a phimosis. This is one of the most important elements in the development of a specific balanitis. In fact, there was no individual in the above list who had been circumcised and only one had a prepuce which remained posterior to the glans. This was one of those listed as very mild and who showed only very slight erosions. It is possible that this man had a recent infection and that within a few days it would have cleared up without medication of any kind. A little soap and water would certainly have been sufficient.

I am convinced that there were other soldiers who had a chronic infection which never developed acute manifestations and so were not detected. It would also seem that some of the acute infections may have dated back beyond the usual period of incubation. This is of course purely a conjecture and at this date can neither be proved nor disproved.

In arriving at a diagnosis one must consider the following: chancre, chancroid, herpes preputialis, ordinary balanitis, tuberculosis, gumma and gonorrhoea. The history of the case, the presence of the characteristic spirochete and bacillus and the type of lesions are sufficient grounds upon which to base a diagnosis with certainty. It is, however, always well to bear in mind the possibility of a mixed infection. In the absence of additional information it is an impossible task to undertake from the study of a stained slide,

the identification of the different spirochetes which may appear in this area. The difficulties are less under the dark field. *Spirochaeta buccalis* resembles *Spirochaeta Vincenti* so closely that such differentiation becomes impossible in the stained slide. There are also *Spirochaeta refringens*, *Treponema dentium* and *Treponema mucosum*, all of which may be found upon the mucous membrane of the penis. They are never present in such great numbers and are not necessarily accompanied by *Bacillus fusiformis*, nor will the *Treponemata* stain so readily as the *Spirochaeta*. *Treponema pallidum* is a much finer organism with more regular and closely wrapped spirals and does not stain so readily and takes more of a blue color while the others are inclined to be a little reddish when stained with either Wright's or Giemsa's stain. It is a difficult matter to stain the spirochete of syphilis with Wright's stain and a period of hours is required with Giemsa's and if there be few *Treponemata* in the dark field there will probably be none in the stained slide.

The fact that a few *Spirochaeta Vincenti* may happen to be present upon the surface of a lesion is not sufficient ground upon which to base a diagnosis. The sore must be well cleaned off and a smear or fluid obtained from the living tissue. It is well to remember that a chancre exudes serum. The presence of a predominating number of *Spirochaeta Vincenti* indicates an infection with that organism but it does not rule out a mixed infection. It should not be hard to diagnose a typical case of erosive and gangrenous balanitis but it may be a matter of extreme difficulty to exclude the presence of syphilis. In 20 per cent of the cases reported in this paper, syphilis was also present and in 6 per cent it was found only at a later examination. One can best secure a mental picture of Vincent's spirochete through dark field examinations of characteristic throat infections.

When one has secured a mental picture of Vincent's spirochete, it becomes a quicker and easier matter to establish a diagnosis with the aid of the dark field taken in conjunction with the clinical picture and the history of the infection.

In the treatment of serious infections, the first and most important step is to make a dorsal slit and open up the infected area to the oxygen of the air. When this is once accomplished the treatment of either the erosive or ulcerative types is not ordinarily a complicated or difficult matter. A 1 per cent solution of silver nitrate applied four times daily has a salutary effect upon the lesions. A 5 per cent solution of potassium permanganate applied as hot as can be endured is also efficacious. Probably the most efficient local application is a 20 per cent solution of chromic acid which should be applied directly with a swab. It should be allowed to remain for one minute and then washed off with hydrogen peroxide. This application does not have an injurious effect

upon normal tissue or membrane. The local application of 5 per cent arsphenamine in glycerine also produces good results. In fact there is on the market a preparation of glucose-arsphenamine which is well adapted for this purpose. This is, however, not good routine practice in genital infections due to the possibility of covering up an incubating initial lesion of syphilis. This same objection does not hold to its use in mouth or throat infections.

When the infection has invaded the deeper tissues and gangrene has taken place, local measures may not serve to control the process. In such cases the intravenous injection of arsenamine is advised. The effect will be quickly apparent. Two or three injections may be required but one will ordinarily suffice. Bloodgood<sup>13</sup> recommends highly the use of a paste of sodium perborate. This should be spread over the affected area and allowed to remain for five minutes and then washed off with warm water. I am informed by Dr. Harry Meyersburg of Brooklyn, N. Y., that in a number of severe infections of the throat which did not respond to the usual methods of treatment, he was able to secure prompt resolution through the use of the mercury vapor quartz lamp. I can see no reason why this same treatment should not be equally beneficial in the same type of infection of the genitalia.

Mild infections which are entirely superficial will yield to soap and water but reliance had better be placed upon some stronger agent. It is believed that such measures are more applicable to prophylaxis than to treatment. In a small series of superficial genital infections it was possible to demonstrate the beneficial effect of such treatment but the progress was not so rapid as with the stronger applications.

#### DISCUSSION

During the last thirteen years the writer has been interested in the spirochetes, more especially those of syphilis, yaws, relapsing fever, those commonly found in the mouth and Vincent's spirochete. From the evidence available it would appear that there is a greater incidence of Vincent's infections now than before the World War and it would appear probable that the returning soldiers may have had something to do with spreading this infection. With a relatively small opportunity for observation during the last three years, one case of erosive and gangrenous balanitis was seen in a soldier who had acquired it in New York City. On account of a profuse discharge coming from a phimotic prepuce, he was sent to the laboratory for confirmation of a tentative diagnosis of gonorrhoea. It was a matter of surprise to learn from those in charge of one of the large venereal clinics in New York City, that they do not have any of the infections. This is a most excellent clinic where great attention is given to

detail and each patient given a close examination. This is a matter which is difficult to explain.

From a period of observation extending over two years it was apparent that both oral and genital infections of this type are far more common in Germany than in the United States and that their incidence is favored by overcrowding, uncleanliness and the scanty use of soap. Genital infections did not appear in circumcised males nor so far as I can now remember have I ever seen a throat infection in any person where the tonsils had been completely removed, nor in gums devoid of either natural or artificial teeth. Favorable conditions such as these are necessary for the spirochete to start growth upon or in the human body or in which to remain quiescent between acute attacks. This focus must be protected from the oxygen of the air and have warmth and moisture. However, where the virulence is high or the resistance low, the organism having secured such a foothold may spread by both lymphatics and contiguity to the surrounding superficial and deep structures. The spirochetes receive adequate protection through their location beneath the surface. Genital infections are not ordinarily severe except in those having a phimosis or a redundant prepuce, which favors the development of an uncleanly condition and furnishes the anaerobic condition necessary for the development of lesions in this location.

Infection of the male genitalia, as has been stated, probably comes about most often as a result of sexual intercourse but this is not essential and for that reason erosive and gangrenous balanitis is not of necessity a venereal disease. Where an individual has a coincident chronic infection of the gums or tonsils, one would hardly be justified in formulating a diagnosis of venereal infection in the absence of a history of exposure. Where the conditions are favorable, it is not difficult to see how an infection might be acquired innocently, especially if the patient already has an infection of the mouth or throat. It is also easy to see how a person might just as readily have a chronic infection of the preputial sac as of the oral cavity, and how under favorable conditions this might flare up into an acute condition. If, on the other hand, there is neither a history nor evidence of an infection elsewhere, it would seem more probable that the infection is venereal in origin. The history of exposure is most important in any case. In those infections where there is a combination of both *Treponema pallidum* and *Sp. Vincenti*, one would be compelled to assume that it is venereal in character.

It is a difficult matter to explain the comparative rarity of such lesions in the female especially when it is obvious that a considerable portion of these infections are venereal in character. It may be that the vaginal secretions have some effect in protecting the tissues from damage. It would appear that the vagina should offer favorable con-

ditions for the development of the disease. From all the information which was available it does not appear probable that any appreciable percentage of the infections listed was due to unnatural practices.

During the period in question the authorities were compelled to combat a continuous influx of prostitutes from several hundred miles in all directions. This was not, however, the greatest problem since these women were picked up within a short time and either confined if diseased, or otherwise, deported. Among the lower classes the standards of morality are perhaps a little below those with which we are familiar in the United States. The social and economic conditions also were such that the relatively affluent American soldier had little difficulty in securing female society not averse to complying with his wishes. As a consequence the moral standards were not very high. The soldiers who were most loose in their sexual habits were as a rule the ones whose habits of cleanliness were the most open to criticism and it became a rather difficult matter in all cases to determine the source of infection. It would seem to be beyond question that the ordinary methods of venereal prophylaxis should be equally as efficacious in this disease as with syphilis and gonorrhoea.

### CONCLUSIONS

- 1 Infections caused by the spirochete of Vincent are far more common among the poorer classes of Europe than in the United States, but since the World War there has been an increase in the United States.
- 2 Erosive and gangrenous balanitis is one of the less frequent manifestations of infection with this organism.
- 3 Predisposing conditions are lack of cleanliness and scanty use of soap. Soap applications are sufficient in themselves to destroy the surface organisms of this disease as well as that of syphilis and yaws.
- 4 The disease does not appear on the genitalia of the circumcised male.
- 5 Vincent's spirochete requires anaerobic conditions for its development and proper growth and the formation of lesions. These exist beneath a redundant or phimotic prepuce.
- 6 These spirochetes may exist in the apparently normal mouth without acute manifestations of their presence. The same condition may exist beneath a redundant foreskin.
- 7 Erosive and gangrenous balanitis is not of necessity venereal in origin though usually so. In the presence of a chronic mouth infection and in the absence of a history, one would not be justified in considering the infection as necessarily venereal in origin.
- 8 The gangrenous type is comparatively rare but when present, requires immediate and strenuous treatment.

9 The standard methods of venereal prophylaxis are equally efficacious in preventing the appearance of erosive and gangrenous balanitis

10 Vincent's spirochete along with *B. fusiformis* may be present upon the external female genitalia or in the vagina but rarely presents acute manifestations. The vaginal secretions may serve to protect

11 This disease is particularly prone to attack lymphoid tissues and follows lymphatic channels

12 From evidence furnished by pathologists as well as the effects secured from definitely spirocheticidal drugs, it seems beyond question that the spirochete is the cause of the injury accomplished in Vincent's infections. There is no evidence that the bacillus is concerned in the acute process unless through symbiosis

13 Except in the case of an emergency it is not good practice to use arsphenamine in the treatment of genital infections

14 The exclusion of syphilis may be more difficult and is more important than the diagnosis of erosive and gangrenous balanitis

## TUBERCULOSIS OF THE ABDOMINAL LYMPH NODES IN EARLY LIFE\*

By JOHN LOVETT MORSE, A.M., M.D., BOSTON, MASS

**T**UBERCULOSIS of the abdominal lymph nodes is presumably due, in the vast majority of cases, to infection with the bovine bacillus. The type of bacillus causing the infection is, however, unimportant, except as regards prevention of the disease. This must consist essentially, of course, in the elimination of tuberculous cows and the pasteurization of all milk which does not come from cows free from tuberculosis.

In this paper I shall not discuss tuberculosis of the abdominal lymph nodes complicating tuberculous peritonitis, secondary to tuberculosis of the intestines or a part of chronic diffuse tuberculosis. I shall consider only those cases in which it is apparently the only lesion. In these cases, however, the tuberculosis of the lymph nodes is probably almost always secondary to a primary lesion of the intestine this lesion having healed and showing no clinical signs. The condition is parallel to that in tuberculosis of the tracheobronchial lymph nodes, in which it has been shown that there is always a primary lesion in the lungs, which has healed and gives no physical signs. Cases of this type are much more common than is usually supposed. Tuberculosis of the abdominal lymph nodes is, however, much less common than tuberculosis of the tracheobronchial lymph nodes. Either the mesenteric or the retroperitoneal nodes may be involved alone or both may be affected simultaneously.

In most instances the symptoms are general and constitutional rather than local. It is relatively uncommon to have symptoms pointing directly to the digestive tract. When the mesenteric nodes are involved, they are seldom enlarged enough to interfere with absorption through the lymphatics. Tuberculosis of these nodes, however, not infrequently causes abdominal pain and discomfort. The nodes are not often enlarged enough to mechanically interfere with the passage of the intestinal contents and cause constipation. They may be, however, in rare instances. They may break down and form mesenteric or retroperitoneal abscesses.

As already stated, the symptoms of tuberculosis of the abdominal lymph nodes are, as a rule, simply those of a mild disturbance of the nutrition and general well being. The child does not seem as well as usual, is not as lively, is easily tired and is irritable. It does not get on as well at school, its appetite falls off and it does not gain or loses weight. A baby does not smile and coo as much as usual and is less active. Pallor or sallowness of the skin develops and the skin and hair are dry. The temperature is a little elevated especially at night—sometimes continuously, sometimes intermittently. The digestion may or may not be somewhat disturbed. If it is, there is usually nothing characteristic about the symptoms. Occasionally, however, the stools may show an intolerance for fat. I have seen several

\*Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N. Y. May 11 1927.

such cases This may happen when there are no palpable nodes

Whenever a baby or child is not thriving, does not seem well and there is no apparent cause, tuberculosis of the abdominal lymph nodes should be thought of as a possible explanation of the symptoms If there is also a little fever, it should be considered more seriously It must not be forgotten, however, that there are many other causes for disturbance of the nutrition and general condition, such as insufficient or improper food, lack of air and sunlight, late hours, excitement and fatigue from either physical or mental overexertion Other obscure diseases, especially those of the fauces, nasopharynx and their annexa, as well as pyelitis, may cause similar symptoms If the tuberculin test is positive, no other foci of tuberculosis are found on physical examination and no evidences of enlargement of the tracheobronchial lymph nodes or of tuberculosis of the lungs are shown by the Roentgen ray, and no apparent cause for the symptoms is made out in the child's life and routine, there is a reasonable probability that the trouble is tuberculosis of the abdominal lymph nodes Even under these conditions, however, it is possible that the positive tuberculin reaction may be due to some hidden focus elsewhere in the body If the tuberculin test is negative after several trials, it is certain that the symptoms are not due to tuberculosis of the abdominal lymph nodes, because, this being a chronic condition, the tuberculin test is sure to be positive

The general constitutional symptoms which have just been described, are not infrequently accompanied by pain and discomfort in the abdomen There is nothing whatever characteristic about the abdominal pain in tuberculosis of the abdominal lymph nodes It may be situated anywhere in the abdomen, may be dull or sharp, fairly continuous or intermittent There is also nothing characteristic about the feelings of discomfort in the abdomen They differ in no way from those common to all sorts of indigestion Under the conditions defined above, however, the presence of abdominal pain and discomfort counts strongly in favor of tuberculosis of the abdominal lymph nodes

When, with the symptoms detailed above, large lymph nodes can be felt in the abdomen, the diagnosis of tuberculosis of these nodes is almost certain It must be remembered, however, that neither enlarged mesenteric or retroperitoneal nodes can be felt unless the abdominal wall is relaxed Enlarged tuberculous mesenteric lymph nodes are easier to feel than enlarged retroperitoneal nodes There may be only two or three or many They may vary in size from that of a small pea or bean to that of an English walnut

They feel elastic or hard, are usually regular in outline, are almost always somewhat movable and are seldom tender They may be felt anywhere

in the abdomen Enlarged retroperitoneal nodes are most often felt in the right iliac fossa or in the median line in the neighborhood of the navel They are, of course, always deep down It is difficult to feel them unless they are at least as large as marbles They are usually missed unless there are a number together They are not movable and are more often tender than are mesenteric nodes They may sometimes be felt through the rectum The Roentgen ray does not show anything definite, when the mesenteric or retroperitoneal lymph nodes are involved, unless there is calcification It must never be forgotten that enlargement of the mesenteric and retroperitoneal lymph nodes does not of itself mean tuberculosis, because the enlargement may be due to other causes, such as simple hyperplasia from inflammation of the intestines and, in rare instances, malignant disease, leukemia, or pseudo-leukemia There is nothing about the feel of the glands which is in any way different, when the enlargement is due to other causes Masses of feces in the intestines may also be mistaken for enlarged mesenteric nodes Masses of feces are usually more movable, larger and less regular in outline than enlarged nodes They can sometimes be changed in shape by pressure, while enlarged nodes cannot Masses of feces disappear after the bowels are thoroughly cleaned out, while enlarged nodes usually become more evident.

In other instances, the symptoms referable to the digestive tract may be more marked Attacks of vomiting are not uncommon and constipation may be quite troublesome Sometimes it is chronic, sometimes intermittent In these cases, the tuberculous process is usually confined to, or, at any rate, more marked in, the retroperitoneal than the mesenteric nodes In these cases a diagnosis of some congenital malformation of the intestine, adhesions from disease of the appendix or chronic appendicitis is often made These diagnoses are not infrequently corroborated by the Roentgenologists, who have, in my own experience, several times described in detail what type of malformation was present or where adhesions were located In these cases, however, operation has shown that none of these conditions were present and that the whole difficulty was tuberculosis of the retroperitoneal and sometimes of the mesenteric lymph nodes In other instances, in which similar diagnoses were made, where no operation was done, the children have recovered and Roentgenographs taken years later have shown calcification of the abdominal lymph nodes It is interesting that in none of these cases have the Roentgenographs shown any evidences of enlargement of the abdominal lymph nodes

In other instances, tuberculosis of the retroperitoneal nodes is associated with pain and the nodes are definitely tender on palpation These

symptoms may come on acutely and may be associated with other symptoms of disturbance of the digestive tract and with a rise in temperature. The first time that this happens, the condition is very likely to be mistaken for acute appendicitis, when there is a history of similar attacks in the past, for recurrent appendicitis. The diagnosis is not very difficult, if it is known that the child has tuberculosis of these nodes. If it is not known, the diagnosis is often very difficult. When the symptoms are acute, there is more likely to be a polynuclear leucocytosis in appendicitis than in tuberculous adenitis. The temperature is likely to be higher in appendicitis and the child to appear sicker. The tenderness may be the same in both. There is localized spasm in both. To the skilled hand, however, there is a slight difference in the spasm in the two conditions. It seems as if it develops on less pressure in appendicitis than in tuberculosis of the retroperitoneal nodes. Rectal examination is not of much assistance, as there is almost certain to be tenderness, and there may be a palpable tumor, in both conditions. The tuberculin test is not of much assistance in these cases with acute symptoms, because the diagnosis and the decision as to an operation must be made at once. I have seen a number of cases of this type in which the diagnosis of a pendency, in several of which I concurred, was made and operation was performed. I have seen a number of others in which operation was considered, but put off, and in which, after the acute symptoms had subsided, enlargement of the retroperitoneal nodes was found and a positive tuberculin test obtained. In doubtful cases, it is, of course, wiser to operate than not, because it does no harm to operate in tuberculosis of the retroperitoneal lymph nodes and the operation reveals a condition which is not suspected and, therefore, would not be properly treated, while, if the real condition is appendicitis, and no operation is done, death is likely to occur as the result of delay.

In rare instances tuberculous mesenteric nodes may break down and form an abscess in the mesentery. In one case of this sort, which I saw, the tumor was about the size and shape of an eggplant. There is, of course, nothing about the physical signs of a tuberculous abscess of the mesentery to distinguish it from other tumors of the mesentery containing fluid. In general, however, the disturbance of nutrition is likely to be greater with a tuberculous abscess than with cysts due to other causes. A tuberculous abscess may also be confused with an ovarian cyst. As a rule, however, an abscess of the mesentery is nearer the median line and higher in the abdomen than an ovarian cyst. Rectal examination may also help in determining the origin of the tumor. A mass of tuberculous retroperitoneal nodes may also break down and form an abscess, which may be mistaken for an appendicial, perinephritic or

psoas abscess. The onset is likely to be much more acute with an appendicial or perinephritic abscess than with an abscess due to tuberculous retroperitoneal nodes. With a psoas abscess, there are always evidences of disease of the spine both on physical examination and with the Roentgen ray.

The prognosis of tuberculosis of the abdominal lymph nodes is, on the whole, very good. It is probable that, in the vast majority of cases, recovery takes place without any suspicion of the condition having arisen. In many of these cases, it is also probable that there never have been any symptoms. In others, there may have been a period of impaired health or nutrition in which the disturbance was attributed to some other cause, like indigestion, overfatigue, overwork or rapid growth. The prognosis is also very good with proper care in those cases in which the true condition is suspected because of the general disturbance of nutrition and a positive tuberculin test is obtained, but in which no enlarged glands are felt. I have never had a case of this sort which did not recover. Even when the enlarged nodes are palpable, most cases recover under careful treatment and many without any special treatment. The prognosis, however, is not as good in infancy as in childhood. The only cases which I have had die, in private practice, have been infants. Recovery in these cases, when it occurs, is complete. I have a number of patients in whom the diagnosis was proved by operation, who are alive and well after periods varying from ten to twenty years. Many of these children are unusually vigorous and robust. Several of them have become well known athletes. In many instances, the enlargement of the nodes entirely disappears. That is, they are no longer palpable. This has happened in a number of my cases in which the nodes were proved at operation to be tuberculous. In one instance, in which an operation for acute appendicitis was performed years after a previous operation on a mistaken diagnosis, the enlarged nodes were no longer present. In other instances the nodes become calcified. I have one case in which a node the size of an English walnut has become as hard as a rock and is palpable in the same position as it was sixteen years ago. In other cases the calcification has been proven by the Roentgen ray and by operations for other conditions in after years. In rare instances the tuberculous process may extend to the peritoneum or a broken down node may be the source of infection in acute miliary or chronic diffuse tuberculosis. When the process extends to the peritoneum the prognosis is that of tuberculous peritonitis. Extension to the peritoneum or a general infection from the breaking down of a node occurs far more often in infancy than later. In the very rare instances in which a retroperitoneal or mesenteric abscess develops, the prognosis is the same as in other tuberculous abscesses which can be opened and drained.

The treatment of tuberculosis of the abdominal lymph nodes is, of course, essentially that of tuberculosis in general. Infection must be guarded against. Babies and children must be kept away from tuberculous adults. All milk which does not come from cows free from tuberculosis should be pasteurized or boiled. Babies and children with tuberculosis of the abdominal lymph nodes should be kept off their feet, preferably in bed, as long as the temperature is above normal. If the temperature rises, they should be put to bed. They must be guarded against overfatigue. No matter what it is they do, whether work or play, if it tires them or puts up the temperature it must be stopped. It is impossible to overemphasize the importance of rest and the avoidance of overexertion. They should have all the outdoor air possible. They should also have all the sunlight that is possible. The Rollier treatment is especially useful in cases of this sort. If they cannot have the Rollier treatment, either completely or in a modified form, it is advisable to use the ultraviolet rays from either the mercury vapor or carbon arc lamps. It must be remembered, however, that it is possible to use these lamps too vigorously and to do more harm than good. It is also important not to trust too much to these lamps and to forget how much recovery is aided by rest, air, food and sunlight. The tendency at present is to forget how much is accom-

plished with these measures and to give the ultraviolet rays emitted by these lamps too much credit for any improvement which occurs. There is also a tendency to attribute too much of the benefits derived from the Rollier treatment to the ultraviolet rays present in sunlight. It is probable that they are of no more importance than some of the other rays or than the stimulating action of the wind. Food should be forced. There are no special indications as to the kind of diet to be used in this type of tuberculosis. It must be remembered, however, that occasionally there is interference with the absorption of fat, when the mesenteric nodes are involved. The stools should always be examined, therefore, to determine whether fat is being absorbed or not. If it is not, the fat in the food should be cut down. I have had no personal experience with tuberculin in the treatment of these cases. What I have seen of its use in the hands of others leads me to believe, however, that it very seldom does any good and, not infrequently, does real harm. It is far wiser, it seems to me, to trust to out-door air, sunlight, food and good care than to tuberculin. Removal of the enlarged lymph nodes is inadvisable, unless they are causing pressure on the intestines and interference with the passage of the intestinal contents. If abscesses form, they should, of course, be opened and drained.

## SOME PROGNOSTIC VALUES IN THE MEASUREMENT OF INTELLIGENCE\*

By IRA S. WILE, M.D., NEW YORK, N. Y.

THE determination that a child has pneumonia or typhoid fever carries with it a prognostic idea of the relative fatality of these two diseases. Inherent in all diagnoses are certain prognostic values. The measurement of intelligence also possesses prognostic as well as diagnostic import.

The measurement of intelligence is usually stated in terms of an Intelligence Quotient, which represents the ratio between the mental age of an individual as compared with his actual or chronological age. It constitutes, therefore, an index of inherent cerebral power. No measurement of intelligence plumbs more than a fraction of mental capacity, but in-so-far as it serves to give some idea concerning the general intellectual capacity of a child, it possesses definite values.

Intelligence quotients are essentially diagnostic instruments. In most instances they appear to be constant and reasonably unvarying thru life. On the other hand the intelligence quotients may vary under conditions that affect its values. The shifting values are conducive to more definite diagnosis and also offer some prognostic information.

Diagnostic methods are not to be regarded as absolutisms. They yield information that requires interpretation. The intelligence quotient is a helpful guide as are other clinical tests or measures. The presence of a positive Von Pirquet is of less value at the age of seven years than a negative reaction. The positive Shick reaction does not indicate that a child must suffer from diphtheria but merely that he is susceptible to it. Typhoid fever may be present many days before a positive Widal reaction can be secured. The X-ray plate is only a series of shadows whose meaning depends upon the interpretation and the skill and background of the interpreter. Similarly, intelligence quotients are to be regarded as facts to be interpreted as part of a general situation.

Mental measures, in a sense, utilize the light of the brain to find its own shadows. If there be little light there will be little shadow. Every intelligence quotient is an index of at least four things,—what a child can do at a definite age—what he cannot do—what he actually has done—and what he has failed to do. Bound up in the actual measurement is evidence of general intelligence potentials together with evidence of the

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N. Y., May 10, 1927.

utilization of the inherent powers thru some degree of education and training. For the most part, however, the intelligence quotient represents the capacity to meet and solve new problems and situations. At the same time, the intelligence quotient is important prognostically because it also contains suggestions as to what children cannot do; and this possibly is as important as a knowledge concerning what they are able to do.

In the analysis of mental processes it is important to recognize not merely the intelligence quotient as a comparative index of cerebral endowment, but to thoroughly understand the factors entering into its calculation. It is important to understand the mode of determining the mental age and most especially to grasp the nature and meaning of the various tests entering into the methods of establishing it. Particularly for purposes of prognosis it is necessary to study the various elements entering into the estimation of the mental age and the intelligence quotient rather than to fasten upon the intelligence quotient itself as an isolated absolute fact.

Just as repeated temperature determinations are of value in judging the outcome of an acute infection so reasonably frequent repetitions of intelligence tests are serviceable in giving prognostic information. The repetition of tests at intervals of six months or one year and the utilization of various types of intelligence tests are exceedingly helpful in deriving the maximum prognostic worth of such procedures. It is apparent that there is need for some variety of tests in order to meet the various situations peculiar to individual children. It is obvious, for example, that the same types of tests are not serviceable for blind or sighted children or for those afflicted with disabilities in hearing. It is essential, therefore, to have familiarity with tests involving language and the non-verbal performance tests.

Children's efforts in meeting the conditions of intelligence tests provide an opportunity for manifesting attitudes of behavior. Intellectual reactions are not identical in the same individual during periods of health and illness, during hours of mental activity and fatigue, under conditions of high emotionality and calmness. The variations in the internal urges of individual children are in a sense, reflected to some extent in their mode of response to intelligence tests. It is because the actual achievement of scores on intelligence tests is dependent upon inherent powers as modified by reactions to living that prognostic values are obtainable.

Prognoses from intelligence tests give no indication concerning length of life or susceptibility to disease. They are fraught with considerable significance, however, in connection with various physical, mental and moral situations which are definitely related to the possibilities of social adjustment including the potentials for vocational satisfaction.

It is generally recognized that the intelligence tests possess diagnostic and prognostic value in determining mental conditions such as mental deficiency. It is insufficient, however, to regard the determination of an intelligence quotient as merely diagnostic because the relative intellectual level offers numerous prophetic suggestions concerning the functional level of the individual. It is highly necessary from the standpoint of communal and personal service to know more or less exactly the mental level of individual children. More particularly is it requisite to ascertain their greatest strength and weakness as the basis of formulating a system of training that will bring about the greatest development of their intellectual resources. In this sense, the intelligence tests are prognostic of the economic and social levels likely to be assumed. This is particularly bound up in the broad differential prognoses that are bound up in diagnosing children as idiots, imbeciles, or morons. It is, however, equally important to realize that children of normal mentality have certain reasonable limitations in their powers of educational growth and development incidental to their inherent intelligence. A dull normal child, for example with an intelligence quotient of 85, whose parents are seeking to make of him an engineer, a school teacher, a lawyer or an executive can be saved much difficulty and disappointment because the intelligence quotient indicates his incapacity to receive the training necessary for such vocational ends. To know what one can become is to learn one's own limitations, and in general terms the prognostic worth of knowing what one cannot do is as important as knowing generally several fields in which one may succeed.

Only a comparatively small proportion of mental deficiency is due to hereditary causes. The largest proportion of our mental incompetents have arisen from natal and post-natal causes. It is all the more important, therefore, to ascertain the mental levels of children whose condition is due to accident or illness, in order to appreciate their possibilities under special forms of individualized education.

Emotional differences and conflicts may profoundly effect intellectual activity and numerous fluctuations of the IQ attest the disturbances entering into mental function. If, therefore, on repeated examinations one finds shifting values of the IQ, it is obvious that one ascertains directly an effect of the mental unrest. An IQ in the same child may vary markedly at different times. For example, a girl with marked mental conflicts on several occasions presented intelligence quotients of 110, 135, 120, 115 and 130. It is evident that the highest IQ represents the truth concerning her mentality and that the lower values suggest interferences with mental function. The stabilizing, therefore, of the intelligence quotient at its maximum was indicative of a cessation of the mental disturbance. Numerous incidents

might be cited to illustrate that the stabilizing of the intelligence quotient is strongly suggestive of a release from emotional conflict

Constantly lowering intelligence quotients upon repeated observations is of serious import as an indication of mental deterioration. This is particularly important in connection with epilepsy, encephalitis, meningitis, primary or secondary, and after traumatic injuries of the head

In the purely physical fields intelligence measurements are of considerable value. They may indicate the cessation of deterioration, an improvement in the basic physical condition or the value of medication or training. For example, a cretin, 6-4/12 years old, who has been taking thyroid substance from the age of 3 months was found to have an I.Q. of 45. This indicates the inadequacy of the medication and the failure of cerebral development more definitely than one could determine merely by observation of the child's particular physical difficulties. In sharp contrast for prognosis, for example, one may consider a 13 year cretin with an I.Q. of 83, which places him in the category of children with slow but reasonably normal type of mental endowment, and considerably above the plane of mental deficiency. Facially, there is evidence that his cretinism has not been fully overcome. The prognosis for this boy, however, is distinctly favorable in view of the high intelligence quotient for his particular type of disease

In congenital lues, the effect of the anti-luetic medication is important in terms of the possible intellectual development of the child. A boy 8-8/12 years old, revealed an intelligence quotient of 65, and there was a serious question concerning his educability. There had been practically no anti-luetic treatment. At the age of 9-6/12 years his intelligence quotient had risen to 77 and at 10-5/12 years to 80.8, and there is every indication of the improvement of his intellectual status as a result of vigorous anti-luetic treatment despite the fact that his Wasserman test has not been reduced below 2 plus. The prognosis now is definitely favorable with the possibility of higher mental attainment on the basis of more successful therapeutics. It is evident that in congenital lues at least the intelligence quotient gives some insight as to the successful influence of the arsenical and mercurial medicaments

A child at the age of 5-5/12 years presented an intelligence quotient of 74, which is suggestive of a borderline deficiency. His fundamental condition was rachitis with moderate hydrocephalus or an encephalitis, or a traumatic process arising at or soon after birth. His physical development was fairly adequate and he was given definite educational training and direction. At the age of 6-4/12 years he manifested an intelligence quotient of 81 which is highly suggestive of the benefit of specialized training and led to a more favorable prognosis concerning his ultimate intellec-

tual capacity and this judgement was further justified by finding his intelligence quotient to be 86 at the age of 8-3/12 years. The change in the mental potentials from 74 to 86 within 2½ years defined his gain in intellectual power. Inasmuch as his intelligence quotient is still rising one can not state that his cerebral potentials have actually been determined. At the present time, however, one is fairly justified in prognosticating normality even though of a dull type. This is far more encouraging than to dwell upon the picture of possible mental deficiency as was suggested by the first mental test

Another moral may be injected at this time, that irrevocable decisions as to children's mentality should not be founded upon a single intelligence measurement, particularly in children presenting physical phenomena as part of the general picture. To stigmatize a child as mentally deficient without a warranting basis is harsh and unjust. Adequate observation with retesting in many instances saves some children from being penalized by absolute prognostications as to deficiency on the basis of a single intelligence quotient

The most important prognostic factor in spastic paralysis probably is the state of the mentality. The production of mental deficiency by reason of intracranial damage is the most dire result of the cerebral palsies, natal or post-natal in origin. All too frequently little effort is made to secure early training of the victims of birth palsies, and at first testing the intelligence quotient may be found exceedingly low. Under educational direction an increase of the intelligence quotient may be noted and as long as there is progress notable in a raised intelligence quotient one may feel justified in continuing a favorable outlook. As soon as the intelligence quotient reaches its limit and there is no further advance one can be certain that the full extent of the intellectual potentials has been achieved. There arises a sort of plateau of mental development after which the advancing years of the child tend to reduce his intelligence quotient. This fact must be borne in mind because a child may, for a period of time, appear to be practically normal intellectually, and then after having reached his intellectual limit he becomes relatively outclassed by comparison with the further mental development of other children of his own age and not thus handicapped. For example, a boy with spastic paraplegia, 7-4/12 years of age revealed a mental age of 4-4/12 years, giving him an intelligence quotient of 59. This was highly suggestive of a middle grade moron. A prognosis based upon this interpretation would have been distinctly hazardous as may be judged by the fact that, at the age of 8 years, he revealed a mental age of 5-10/12 years, giving him an intelligence quotient of 73, placing him in the group of children who are regarded as borderline mental defectives. At the age of 9 years he had

a mental age of 6-10/12 years with an intelligence quotient of 76. The fact that this boy's intelligence quotient is still rising indicates that he has not yet achieved the maximum development of his cerebral potentials, but in all probability has been taken out of the mentally deficient group.

A girl who suffered a hemiplegia as a result of an embolism following a blood transfusion, at the age of 9-10/12 years revealed a mental age of 8-4/12 years, giving her an intelligence quotient of 85, placing her among the category of children apparently below normal. This child previously has been bright and capable, and the mere statement of her intelligence quotient gives no picture of the degree of brain injury that she had suffered. At the age of 10-9/12 years she evidenced a mental age of 10-2/12 years, with an intelligence quotient of 94.5. This marked rise in her intelligence gave a better indication of her growth and a further picture of her general improvement. For a period of time this represented her actual growth and development. Her mental age at 10-9/12 years almost reached its completion. Her mental age finally attained 10-7/12 years and this continued with practically no progress. Her stationary mental age with increasing chronological age brought about a reduction of her intelligence quotient so that it actually became lower than it was at the time of the original testing, five years previously. With a chronological age of 14 years and a mental age of 10-7/12 years she had a consequent intelligence quotient of only 76. This illustrates the necessity for considerable caution in utilizing the intelligence quotient for prognostic purposes. The relative development of normal children represents many problems but these are markedly intensified when one is dealing with severe pathological processes. At the same time the need for repeated measurements of intellectual power is emphasized by such variations as I have indicated.

After encephalitis one often notes a marked decrease of the intelligence quotient, which is entirely unrelated to the duration of the attack. It is impossible to indicate the entire mental power in terms of the intelligence quotient. All too frequently the emotional disturbances incident to the disease hamper attention, interfere with normal function and are responsible for a lowering of the intelligence quotient. There is little relation between the intelligence quotient and the curability of the child. The personality alterations which may ensue as a result of the encephalitis process are of more profound importance than the intellectual capacity. A girl, for example, with an intelligence quotient of 103, representing intellectual normality, evidenced a very marked loss of control over her sexual inhibitions. Her emotions and her fantasies precluded marked activity in study and tho she had a normal intelligence her school development was practically negligible. Numerous cases might be cited to indicate that

the intelligence quotient possesses comparatively little value in prognosticating the final outcome of encephalitis insofar as behavior or personality is concerned. There is a gradual raising of the intelligence quotient as the emotional elements subside and as the sub-acute inflammatory conditions pass away. More significance lies possibly in the spread of the elements entering into the mental age than in the intelligence quotient itself. But this need not be discussed at this time. It may be said, however, that the spread and distribution of the psychological powers in encephalitis frequently is similar to such changes as are found in chorea, hysteria and occasionally epilepsy.

The intelligence tests usually reveal an arrested mental post-encephalitic development and thus far in my experience they appear to show more marked effects in the presence of the Parkinsonian syndrome. A rise in the intelligence quotient during convalescence from this disease is highly suggestive of general improvement.

It is noteworthy that in chorea, even tho the physical state may appear to have cleared, often the psychical influences may still be detected through the determination of the intelligence quotient. A stabilized intelligence quotient is an excellent indication of the adequacy of the cure of chorea.

Ordinary goitre of the adolescent type or even the early stages of endemic goitre appear to reflect very little change in the intelligence quotient. Exophthalmic goitre shows an irregularity in the intelligence quotient largely due to difficulties in attention, excitability and other emotional components. Goitre surveys indicate comparatively little difference between the intelligence levels of children showing mild goitres and those whose thyroid glands are not enlarged.

The presence of hookworm infection is marked by a lowered intelligence quotient. The improvement in the general physical condition as the result of therapeutics is manifested by the improved intellectual power as evidenced in the raising of the intelligence quotient. Intelligence tests may serve as an aid to the microscope in determining the prognosis for children who have had the hookworm infection.

Intelligence tests are serviceable following contagious diseases, and not only when meningitis has been a sequela. After scarlet fever, for example, when there may be some impairment in hearing or vision, the physical examination should reveal the difficulty. At times, however, the child is first seen after his failure in school work and then the intelligence tests may be very important. Recently, a 7-6/12 year old boy was seen because it was feared that he was mentally deficient. With a chronological age of 7-6/12 years he revealed a mental age of 6-11/12 years, giving him an intelligence quotient of 92, which indicated normal average mental ability. It was patent that the child was not mentally de-

ficient and the monotony of his voice suggested impairment of hearing. Further examination revealed the loss of approximately 40 per cent in each ear. The cause of his aural difficulty had been otitis media following a contagious disease. The entire prognosis of this child's future was altered by a direct knowledge of his normal intellectual function, even tho special training in lip reading will be requisite because of his impaired hearing.

I might enumerate many other conditions in which mental measurement is of service, but I am concerned merely with a general presentation of the value of this procedure to pediatricists. Intelligence tests are of service in relation to problems of delinquency. In many instances the lower intelligence quotient is found in delinquency of the less serious type. Possibly there are fewer children with superior intelligence quotients among delinquents as compared with the general population because a more highly intelligent group is more successful in escaping capture. The prognosis concerning the reform of delinquents, however, is not markedly altered by a knowledge of their intelligence quotients. A low intelligence test does not adequately explain all forms of misbehavior as truancy, theft, lying

and petty crimes. Maladjustments as a whole are more responsible. Mental tests in no wise are to be regarded as prognostic of the after success of delinquents subject to so-called reform methods.

The pediatrician will find considerable value in mental measurements for prognosticating the intellectual development of the children under their care, and for securing the data most necessary for providing an adequate school adjustment. Under no circumstances, however, are mental measurements to be regarded as fetishes. They are not objects of adoration, but instrumentalities to be employed. Properly used they afford valuable knowledge concerning one phase of juvenile activity. The intelligence test is a measure of intellectual potentials and of nothing else. To the extent that cerebral function is conditioned by bodily ailments there will be some evidence of the effect of disease upon the ability to learn, recall and recreate. There is much need for careful study of the relation of the intelligence quotient to various acute diseases so as to take out of the realm of theory and guess many influences which can be more or less accurately determined. It is to stimulate a greater interest in this medico-psychological relationship that I stress the value of intelligence testing in prognosis.

## THE INCOMPLETELY DILATED CERVIX\*

By PAUL T. HARPER, M.D., ALBANY, N. Y.

THE discussion has to do with cases incompletely dilated when the necessity for active treatment arises. In other words, cases considered are those wherein the patient is in a clinical second stage with frequent, prolonged and variably propulsive contractions or those, with internal os as yet unobliterated, wherein contractions are frequent, prolonged and unusually painful.

In either event active treatment is demanded in the interests of the mother or the child, or both. Late inertia with the probability of undue postpartum blood-loss is the danger confronting the mother, while intra-uterine asphyxia from interference with the utero-placental circulation is the foetal hazard attendant upon long-continued, strong contractile efforts.

Cases wherein incomplete dilatation is due to slow although uneventful labor or to secondary inertia are excluded. Uterine under-action characterizes them, while in those under discussion *uterine over-action* is the outstanding feature.

Incomplete dilatation met in *active* labor is due to one of two causes: *first*, conditions mechanically interfering with progressive dilatation and, *second*, inherent rigidity.

Since 'rigidity' is so familiar a term, failure

in dilatation due to structural abnormalities will be considered first. Among them are:

(a) *Muscle Fibres Replaced by Connective Tissue*. But this characteristic would be shared to some extent by the rest of the uterine muscle and the whole structure would become impaired as a working organ. This is doubtless the important factor in some cases of inertia manifest from the beginning of labor. But here it is evident that the difficulty is not due primarily to the fibrous cervix.

(b) *Fibrous Tissue Limited to the Cervix*. Tissue of the kind, the result of chronic inflammation or of injury, would decrease the elasticity of the cervix, and it is doubtless a factor in poor dilatation. However, its importance is not great because practically all 'rigid' cervixes 'relax' when appropriate treatment is applied.

(c) *Malignancy*. This might impair dilatability. But its occurrence is so rare that it is at best an unimportant factor.

(d) *Scar Tissue*. This would seem to be an adequate cause for failure in dilatation, but the process is found to proceed uneventfully even where earlier high circular amputation has been done.

(e) *Lower Segment Adhesions*. This abnormality, the result of a proliferative low endome-

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N. Y. May 11, 1927.

tritis or endocervicitis, invariably retards dilatation. Failure here is purely mechanical, being due to interference with progressive thinning-out of the lower segment and its upward advance over the presenting-part *rather than* to any 'firmness' that the cervix might present to the examining finger.

From what has preceded it would seem that, where 'rigidity' is met, the abnormality is more apparent than real, and that practically all cervixes may be expected to dilate uneventfully unless there are other reasons for failure.

In the overwhelming majority of instances, incomplete dilatation is due to mechanical interference occasioned by one or the other of two groups of causes that are either uterine or pelvic in origin.

#### (A) Uterine Causes of Incomplete Dilatation

First to be considered is General Uterine Retraction. This is a state wherein the uterine musculature applies itself more or less intimately to the furrows and depressions of the foetal outline. Presume the state to be more or less persistent and it is at once apparent that progressive thinning-out of the lower segment and its upward advance over the presenting-part are interfered with and that the cervix fails to undergo progressive dilatation. The state 'persists' when uterine muscle tone is maintained, the cervix and lower segment maintain the same or even more tone, and the cervix *feels* firm, or 'rigid'.

It is characteristic of the lower segment to acquire 'tone' and to maintain it more or less indefinitely. This is so constant *after* delivery that post-partum lower segment retraction is physiological. The examining finger introduced beyond the internal os and well into the uterine cavity invariably meets the thickened lower segment and the Retraction Ring (marking its upper limit) if the post-partum uterus is satisfactory retracted.

But let retraction, even to a far less degree, be set up *before* the escape of the child, and an obstacle not only to progressive dilatation but also to actual delivery of the child is apparent at once. General uterine retraction is a common cause of incomplete dilatation.

But *premature* retraction of the lower segment is highly improbable unless two conditions obtain *first*, escape of the liquor amni (*allowing* the musculature to fit into the depressions and furrows of the foetal outline) and, *second*, frequent and strong contractions (supplying the *active force* that makes the musculature so apply itself).

In malpresentation and malposition, where lower segment retraction and 'rigid' cervix are common, the membranes frequently rupture prematurely, while, with the escape of the fluid, increase in frequency and intensity of the contractions is the rule. Additional causes of lower segment retraction appear in the 'irritation' occasioned by certain oxytocics and especially by measures employed in inducing labor or aiding dilatation.

The lower segment invariably manifests tone after the administration of pituitary extract, and so pronounced is its effect that its routine third-stage use may be followed by so marked retraction that the spontaneously-separated placenta has to be manually extracted through the overactive lower segment and the Retraction Ring. This is especially true where the uterus, earlier in labor, has shown itself to be 'irritable', in that contractions have been atypical as to frequency, duration and the amount of 'pain' occasioned.

The bougie and the hydrostatic dilator not infrequently produce contractile efforts that *appear* to be highly efficient but that are wholly disappointing as far as effecting progressive dilatation is concerned. The cervix should dilate but does not, and lower segment retraction is presented as the probable explanation.

Role of Bandl's Ring as a uterine cause of incomplete dilatation demands attention. Pathological Rings are of two kinds. The Ring that 'rises' because of nature's efforts at expelling the child from a true tonic, or 'capped', uterus, and the Ring that *does not* and cannot 'rise' because of its firm grasp upon the child's body in relation with it. In the latter instance, dystocia is uterine, and the Ring is the primary (uterine) cause of obstruction. It is with Rings of this type that the discussion is concerned.

The Ring appears in tonic *isolated* contraction in the absence of tonicity of the upper segment and retraction of the lower, and to it the term Contraction Ring is appropriately applied. Or the Ring becomes prominent and maintains persistent tone as a part of general uterine retraction. The Ring under these conditions may be designated as the Retraction Ring.

In either case, firm grasp of the Ring on the child's body makes it impossible for it to *rise*. By the same token it is impossible for the lower segment to be drawn further and further upward, and for the cervix to undergo progressive dilatation. Accordingly, *dilatation ceases when grasp of the Ring becomes firm*, and there is *no advance* in dilatation until the Ring disappears.

Unless there is associated lower segment retraction, the incompletely dilated cervix in Ring dystocia does not feel 'rigid'.

#### (B) Pelvic Causes of Incomplete Dilatation

Again the difficulty is mechanical. There is disproportion, due to the fact that pelvic measurements are below normal or to the fact that the child is *relatively* large for the particular pelvis.

Incomplete dilatation met in cases of the kind appears relatively late in labor, commonly during the second stage, at a time when frequent and strong contractions have produced sufficient moulding and descent for the lower segment to be caught and held between the presenting-part and the bony pelvis. Force 'holding' the cervix is stronger than that 'pulling' it up, and dilatation ceases.

Passive congestion is the inevitable consequence of pressure on the cervix, and the parts soon become oedematous. If contractile efforts are strong enough, the cervix becomes markedly thickened, and, with conditions unreheved, it is only a matter of time until the incompletely-dilated cervix becomes "incaerated." Spontaneous dilatation is out of the question, expectancy promises little if any relief, and treatment is active.

The cervix in cases of the kind is usually soft it feel "rigid" only where lower segment retraction is associated. But since malpresentation and malposition may account for the disproportion in the particular case, the possibility of associated lower segment retraction must be constantly borne in mind.

**Diagnosis** The cause of incomplete dilatation must be determined before treatment of the apparent lack of advance may be considered. This is vitally important. To illustrate with incomplete dilatation due to a true tonic Bandl's Ring, complete manual dilatation of the cervix might be simple, but spontaneous advance thereafter would be out of the question and even instrumental advance could not be effected unless excessive tractive force (enough to overcome the firm grasp of the Ring) were employed.

On the other hand, with incomplete dilatation due to moderate pelvic disproportion and cervical oedema, the patient might deliver herself spontaneously following complete artificial dilatation. At any rate, there is no additional cause of dystocia present, and extraction would be accomplished uneventfully.

**Symptoms and Signs** Retraction and Ring dystocia are commonly *late-first-stage* complications; and they are almost always accompanied by atypical contractions.

In *retraction*, the contractions are prolonged, and there is little foetal movement apparent because of close approximation of the uterine walls. Especially significant is the disappearance of pain 'low down in back' indicating progressive dilatation, and the appearance in its place of more or less continuous pain 'low down in front'.

The abdominal signs of general uterine retraction are persistence of 'tone' to the entire uterine musculature in the intervals between contractions, variable tenderness low down in front, and prominence of the irregularities of the foetal outline.

The signs referable to the cervix are as follows: its edge is thickened, it is in intimate contact with the presenting-part because the membranes have ruptured or, if intact, because the fluid is scant, and simple attempts at dilatation meet with marked resistance. The peculiar 'feel' is due to a combination of slight oedema (caused by passive congestion that results from the tight grasp of the lower segment) and muscle-tone that the cervix shares with the rest of the uterus.

In *Ring dystocia*, symptoms are not at all con-

stant. Contractions not infrequently *cease* when the Ring sets itself up in advance of the presenting-part, while it is not unusual for them to become markedly propulsive, and for the fundus to rise as it does during a physiological second-stage contraction, as soon as a Ring has set itself up *behind* the presenting-part.

The only dependable signs of Ring dystocia are those elicited as a result of exploration of the lower segment and palpation of the region of the Ring for evidence of tonicity. An anaesthetic is required.

As the upper portion of the lower segment is reached, the examining fingers are directed sharply toward the uterine mid-line by the lower surface of the Ring. The latter completely encircles the interior of the uterus or it stands out as a prominent crescentic ledge as all or only a part of the circular uterine muscle fibres are involved. The edge of the Ring is sharp and unusually firm when in tonic isolated contraction, and it is rounded, less prominent and less firm when the Ring is a part of general uterine retraction. The inside diameter of the Ring and its firmness determine the extent to which it is obstructive.

For reasons that are apparent, *signs referable to the cervix even in grave Ring dystocia may be negative*.

Incomplete dilatation due to *disproportion* is as a rule a second-stage complication. Symptoms are characteristic, while signs are readily elicited. More often than not, contractions are non-propulsive or, if propulsive, they are insufficiently so. They occur at frequent intervals and they are prolonged, but, with them, the patient bears down ineffectually or she is wholly unable to co-operate as she should. This may be interpreted as nature's effort at conserving the store of uterine muscle energy: late inertia and poor post-partum hemostasis are guarded against by rendering her 'unable' to exhaust her store of uterine-muscle energy through long-continued and ineffectual efforts at 'bearing down'.

A patient in an anatomical second stage bears down whether she wants to or not, while, with a definite obstacle to advance, her efforts are unsatisfactory regardless of her willingness to co-operate.

Signs referable to the cervix are readily elicited. It is in advance of the broad diameter of the presenting-part, rim of the cervix is thickened, it is soft, and it bleeds readily even when only moderately oedematous. It is still thickened but it is far less soft when lower segment retraction is associated.

**Treatment** This is both prophylactic and active.

The essentials of prevention appear in the application of a few general rules.

Guard against lower segment retraction by according the manifestations of 'irritable' uterus (namely frequent, irregular and 'painful' con-

tractions) treatment by sedatives, narcotics and even anaesthetics. This is especially true of cases wherein bougies or 'bags' have been used to induce labor.

In the presence of malpresentation, premature rupture of membranes, and unobliterated internal os, keep the patient in bed to prevent complete draining-away of the liquor amni, control irregularities in uterine contractions by sedatives and narcotics, and institute hydrostatic dilatation as the safest substitute for the bag of waters where contractile efforts (once set up) are abnormal as to frequency, intensity, and the amount of 'pain' occasioned.

Never attempt the dilatation of a 'rigid' cervix until all trace of muscle-tone has been eliminated by deep surgical anaesthesia. Lower segment retraction and even tonic Ring are common results of failure to take this precaution.

Remove a hydrostatic dilator after it has been in position from 12 to 15 hours *regardless* of the dilatation produced. If little advance has been made, retraction is probable while, if contractile efforts have ceased, it is probable that a tonic Ring has formed behind (that is, above) the dilator.

Active treatment has to do with the medication used to control uterine over-action and to remove the uterine obstacles to ultimate delivery, and with operative procedures made use of to compensate for deficiencies in expulsive efforts.

**Morphine.** This has a definite although a mild sedative effect upon over-active uterine muscle. It is sufficiently depressing however to assure satisfactory relaxation between contractile efforts where the latter are only slightly prolonged and where there is but mild tone preserved.

No small benefit comes from its relief of subjective pain, and the latter is a common accompaniment of uterine over-action. Whether it is cause or effect is immaterial. Morphine is said to 'soften' the cervix, but, at any rate, 'rigid' cervixes are found to undergo more rapid spontaneous dilatation after its administration.

Dose is 1/4 gr, usually combined with atropine, or it may be used in correspondingly smaller doses (1/8 to 1/6 gr) when combined with its 'synergist'—magnesium sulphate.

**Inhalation Anaesthesia.** When contractions have lost their intermittency and the uterine musculature fails to relax completely between contractile efforts, even light anaesthesia assures satisfactory relaxation. While, with retraction even moderately advanced, from 15 to 20 minutes of continuous light anaesthesia may be all that is required to re-establish normal uterine action and to effect relatively rapid spontaneous dilatation, the most promising sign of which is a return of mucosanguinous 'show'.

**Rectal Anaesthesia.** With membranes ruptured, with the cervix incompletely dilated, and with contractions frequent, *prolonged* and 'pain-

ful', ether in olive oil by rectum acts almost as a specific in restoring physiological contractile efforts, in relaxing the grasp of the retracted lower segment, and in effecting progressive dilatation. Aside from the relief of unnecessary 'pain' (with its inevitable *relative* shortening of labor), rectal anaesthesia *actually* shortens its duration, and this is doubtless due to the fact that it *assures* satisfactory relaxation in the intervals between contractile efforts.

It is reasonable to contend that a cervix that is 'soft' when a contraction begins will dilate more readily than one possessing tone at the time. Anaesthesia 'softens' the cervix because it removes lower-segment tone.

**Rectal anaesthesia** is invaluable because, by using relatively small and repeated instillations, not only perfect relaxation between contractions but also the frequency, intensity and the duration of the latter can be quite perfectly controlled.

Condition of the internal os has everything to do with the operative measures that may be employed.

With but a remnant of internal os remaining, the patient is still in an *anatomical* first stage, even though frequent, strong and prolonged contractions indicate a *clinical* second.

Indications here are, first, to decrease the frequency and the intensity of the contractions and, second, to aid directly in dilatation. They are best met by rectal anaesthesia (2 ozs for instance) and by introduction of a hydrostatic dilator.

If the patient is a primipara, both procedures are indicated. Manual or digital dilatation may not be attempted because the cervix is not 'ready' for relatively rapid complete manual dilatation. Incomplete thinning-out of the lower segment, with added resistance to advance by forceps or by traction on the breech, and accentuation of lower segment retraction with the possible development of a tonic Ring are the usual consequences of attempts at complete manual dilatation under the circumstances.

If the patient is a multipara, choice lies between rectal anaesthesia (symptomatic sedative treatment) and manual dilatation under deep surgical anaesthesia. The necessity or the desirability for haste is the determining factor.

With the internal os wholly obliterated and the lower segment thin, the cervix is fully dilatable *under deep surgical anaesthesia*, and manual dilatation followed by delivery is indicated. This quite regardless of the extent of dilatation of the external os.

Complete skeletal-muscle relaxation is demanded before digital dilatation may even be begun, and adequate relaxation cannot be *depended* upon until anaesthesia has been carried to the point of beginning pupillary dilatation. It is impossible to eliminate lower segment tone, in only moderate retraction, under less than approximately 20 min-

utes of continuous anaesthesia The writer's experience has been limited entirely to the use of ether in this connection

The manner of effecting complete dilatation depends upon the location of the presenting-part Arrest at the pelvic inlet and, then, at the outlet alone will be considered

With inlet arrest and delivery indicated, it is presumed that internal podalic version and breech extraction will be done The preferable method of dilation is the 'Harris', wherein the finger tips are inserted in the cervix and then widely separated, simulating physiological dilatation Spontaneous dilatation proceeds from within outward

Dilatation is 'complete' for purposes of delivery when—and only when—the loosely-clenched fist can be drawn through the cervix and lower segment with ease Such a test commonly results in raising the presenting-part and it may be disengaged But this is in no way a handicap since delivery is to be effected by version and extraction

With the presenting-part low and the rim of the moderately well dilated cervix palpable, the most satisfactory dilatation is brought about by immobilizing the presenting part by forceps and exerting *upward* digital pressure against the cervix at the height of each contractile effort Rim of the cervix is displaced upward beyond the broad diameter of the head *before any attempt at traction is made*

This is desirable for several reasons First, it simulates the normal mechanism of dilatation wherein the rim of the cervix is drawn upward Second, it eliminates traction on the broad ligaments that is inevitable where dilatation is completed by forcible advance of the blunt head through the cervix Third, it minimizes the amount of tractile force (and incidentally the amount of cerebral pressure) necessary to effect ultimate delivery

With the presenting-part at intermediate levels, dilatation is effected by inserting the tips of the fingers just within the cervix The fingers are gradually separated and the dilating cervix displaced upward Dilatation is done during contraction, and the presenting-part is not displaced upward because it rests in the hollow of the rising hand

Reference should be made to a common abnormality met in multiparous labor Where the outlet is relaxed and the broad ligaments have been stretched, second stage commonly finds the presenting-part in the low mid-pelvis Advance is retarded, and a markedly oedematous anterior cervical lip accounts for the delay If dilatation is just short of complete, attempt should be made to displace the thickened anterior lip upward behind the symphysis and over the presenting-part *in the interval* between contractions Subsequent expulsive efforts accomplish speedy delivery in cases where the second stage would be otherwise unnecessarily prolonged

Before proceeding with operative delivery following artificial dilatation, definite information referable to the condition of Bandl's Ring is invaluable A tonic Ring is a primary cause of dystocia in other words, it accounts for incomplete dilatation Accordingly, dilatation of the cervix is only a step—and the less important one—in operative delivery With the Ring persistent, vaginal delivery is always difficult, and it may be impossible unless excessive and dangerous tractile efforts are made

Lower segment exploration preliminary to extraction is indicated whenever dilatation is incomplete and any of the following abnormalities obtain dry labor, malpresentation or malposition, and relative or actual pelvic contraction

It is imperative after a single unsuccessful attempt at producing advance by traction on forceps or on the breech

## THE SUMMER SEASON

It is a theory that July brings rest and relaxation to physicians. Theoretically doctors are on their vacations during the summer season. This belief leads the writers of medical papers to request that their articles be withheld from publication until fall. The fact is that all seasons are very much alike to most physicians and that only the favored few are able to close their offices

and retire to the mountains and seashore and summer resorts.

Physicians seem to read their summer medical JOURNALS as keenly as those of the winter. If the large number of articles that are in the hands of the editors are to be published within a reasonable length of time they must appear during the summer as well as in the fall and winter.

## ESTABLISHING COUNTY DEPARTMENTS OF HEALTH

There was recently held in New York a conference of representatives of the State Medical Society, the State Charities Aid Association, the State Department of Health, and the State Health Officers' Association

This conference was for the purpose of formulating plans and methods of organizing County Health Departments, and particularly as to who should take the first step toward obtaining for the county this public health benefit by taking advantage of the permissive laws already existing, thus still further improving the splendid health organization in New York State

Two principles were decided upon first, the County Society must originate the movement in the county, second, the best help that can be rendered lies along educational lines

Information must be furnished to the County Medical Society that will enable its members to decide if they want to advocate this new form of organization for public health advancement, and

if they do, to help them to create public sentiment among the constituents of the Board of Supervisors sufficient to warrant the board in establishing a County Health Department, so that for every thousand dollars spent for health purposes the county may receive an equal amount from the state

It was decided to undertake to support definitely the work of two counties already partly prepared for this advance step, and to encourage others that are beginning to show interest in the development of better organization for public health administration

This conference was one of the most sane, sensible and practical illustrations of the value of an unselfish interest in advancing public health organization

It was a concrete expression of the rapid evolution going on in medicine, in public health, and in lay organization this year, and it further shows in a striking way the value of harmony and team work

---

## CIRCLES OF INFLUENCE

Every physician starts waves of influence whose ever widening circles spread in all directions. The reputation which he voluntarily seeks is that which he can capitalize. He wishes to be known for special skill in fevers, or fractures, or other specialties, so that he may be called in consultation by family doctors, and sought by the people generally. The circle of his medical influence will be judged popularly by the number of calls which he receives and the size of his bank account

A minority of practicing physicians seek a reputation along public health lines in addition to those by which they earn their living. A few can write, and their circles of influence may be multiplied indefinitely as other doctors adopt their ideas and methods of practice. Every medical society has one or two writers among its members, and these have opportunities to extend the influence of scientific medicine to all the physicians in the county, and secondarily to every person in the community. The writers have unique opportunities for broadening their circles of influence in medicine, which cannot be marred, even by those who use the articles primarily for advertising purposes

Some doctors delight in talking, and these have a circle of influence which extends far beyond their immediate audiences. When public health measures are under consideration, the medical orator can create a favorable public sentiment even though his medical science is of the popular kind. The medical orator is of increasing importance in these days when public sentiment must be created for hospitals and clinics and

welfare stations, and all kinds of public health prospects

The physician who can speak interestingly may have a circle of influence which is larger than that of his colleague who knows his science better than the principles of medical salesmanship

A doctor makes a great mistake when he thinks that his circle of influence is too limited to be of value. There is a place for every doctor in a county medical society. Every doctor can do something better than any other doctor, and his influence in his own peculiar field overwhelms that of any other doctor in his community. A county medical society cannot afford to exclude any physician except for gross violations of the code of medical ethics. It is even true that the medical profession can control a doctor who is in the society much more effectively than one outside of its influence. The county society has its circle of influence whose test is its power over the doctors of the county

Every physician has a sense of his obligation to practical public health and civic medicine, to some extent at least. He also desires to extend his circle of influence, but often he does not know how to do it along public health lines. The newer activities of county medical societies include methods of extending the circles of influence of the societies through all the physicians and all the people in a community. It is an ambitious program, but new conditions must be met in new ways

The Medical Society of the State of New York wisely leaves the decision regarding local medical matters to the county medical societies, but it

will advise and assist them to make their circles of influence effective. It will supply the machinery which will enable the local society to trans-

form its waves of influence into the driving power which will activate all public health work in a community

---

## THE MEDICAL SERVICE OF THE U S ARMY

The authority of the medical officers of the Army of the United States is now recognized to be as great as that of the engineer, the artilleryman and the aviator. The medical service of the regiment division, the corps and the Army is centered in the medical regiment whose officers are physicians, dentists, veterinarians, pharmacists and business men connected with those professions. The medical regiment of a division consists of over eight hundred men and sixty-nine officers under a medical colonel who is on the staff of the General in command, and whose activities are co-ordinated with those of all other branches of the service.

The United States Army conducts schools for training medical officers in the performance of their military duties. The one nearest to New York State is the Army Medical Field Service School at Carlisle, Pennsylvania, to which over five hundred medical reserve officers are sent each year for two weeks of training.

A two weeks' session has just recently ended,

and another session opened on July third, which is attended by over fifty medical reserve officers from New York State. The doctors live under field service conditions. They room in tents with only such necessities as they can bring in a small trunk. The training is intensive from the point of military medicine, but of equal benefit is the physical training of the men themselves along lines that are like those of a hunting trip in the mountains. Still another benefit is that of meeting some of the leading medical lights of the land under conditions like those in a medical society. There are to be found the deans of medical schools, hospital managers, teachers of surgery, and leaders of medical societies. If a three-day meeting of the Medical Society of the State of New York affords the opportunity for physicians to consult one another regarding their problems, much more does the Army Field Service Medical School enable physicians to gain inspiration from their intimacy with the best medical men of the country.

---

## LOOKING BACKWARD

### THIS JOURNAL TWENTY YEARS AGO

*Personal Hygiene* This JOURNAL for July, 1907, contains an article on personal hygiene in which the author, Dr F DeW Reese, of Cortland, discussed the influence of retained discharges or closed channels, upon neighboring organs of the body. The article is of historical value, for its subjects are very different from those which would be discussed at present, and the suggestions emphasize the progress in medical science during two decades. The subjects discussed were

1 Skin excretion "A closure of the glands of the skin by dirt or from other influences, will load the system with eliminative products"

2 Stricture of the urethra, resulting in en-

larged prostate, cystitis, ureteritis, pyelitis, nephritis, uremia and insanity—a pretty big list

3 Constipation with all the attendant bad results that come from pent up contents of the intestinal tube. Diet and surgery can relieve the larger portion of these patients

4 Uterine discharges

5 Cerumen in the ear

6 Adenoids—"With Gottstem's curette in a dexterous hand, with ethyl chlorid as the anesthetic, the operation for the removal of adenoids, can be performed in two and a half minutes"

7 Tonsillar crypts—slitting them and allowing them to heal from the bottom was the standard procedure recommended by the author

## ESTABLISHING COUNTY DEPARTMENTS OF HEALTH

There was recently held in New York a conference of representatives of the State Medical Society, the State Charities Aid Association, the State Department of Health, and the State Health Officers' Association

This conference was for the purpose of formulating plans and methods of organizing County Health Departments, and particularly as to who should take the first step toward obtaining for the county this public health benefit by taking advantage of the permissive laws already existing, thus still further improving the splendid health organization in New York State

Two principles were decided upon first, the County Society must originate the movement in the county, second, the best help that can be rendered lies along educational lines

Information must be furnished to the County Medical Society that will enable its members to decide if they want to advocate this new form of organization for public health advancement, and

if they do, to help them to create public sentiment among the constituents of the Board of Supervisors sufficient to warrant the board in establishing a County Health Department, so that for every thousand dollars spent for health purposes the county may receive an equal amount from the state

It was decided to undertake to support definitely the work of two counties already partly prepared for this advance step, and to encourage others that are beginning to show interest in the development of better organization for public health administration

This conference was one of the most sane, sensible and practical illustrations of the value of an unselfish interest in advancing public health organization

It was a concrete expression of the rapid evolution going on in medicine, in public health, and in lay organization this year, and it further shows in a striking way the value of harmony and teamwork

---

## CIRCLES OF INFLUENCE

Every physician starts waves of influence whose ever widening circles spread in all directions. The reputation which he voluntarily seeks is that which he can capitalize. He wishes to be known for special skill in fevers, or fractures, or other specialties, so that he may be called in consultation by family doctors, and sought by the people generally. The circle of his medical influence will be judged popularly by the number of calls which he receives and the size of his bank account

A minority of practicing physicians seek a reputation along public health lines in addition to those by which they earn their living. A few can write, and their circles of influence may be multiplied indefinitely as other doctors adopt their ideas and methods of practice. Every medical society has one or two writers among its members, and these have opportunities to extend the influence of scientific medicine to all the physicians in the county, and secondarily to every person in the community. The writers have unique opportunities for broadening their circles of influence in medicine, which cannot be marred, even by those who use the articles primarily for advertising purposes

Some doctors delight in talking, and these have a circle of influence which extends far beyond their immediate audiences. When public health measures are under consideration, the medical orator can create a favorable public sentiment even though his medical science is of the popular kind. The medical orator is of increasing importance in these days when public sentiment must be created for hospitals and clinics and

welfare stations, and all kinds of public health prospects

The physician who can speak interestingly may have a circle of influence which is larger than that of his colleague who knows his science better than the principles of medical salesmanship

A doctor makes a great mistake when he thinks that his circle of influence is too limited to be of value. There is a place for every doctor in a county medical society. Every doctor can do something better than any other doctor, and his influence in his own peculiar field overwhelms that of any other doctor in his community. A county medical society cannot afford to exclude any physician except for gross violations of the code of medical ethics. It is even true that the medical profession can control a doctor who is in the society much more effectively than one outside of its influence. The county society has its circle of influence whose test is its power over the doctors of the county

Every physician has a sense of his obligation to practical public health and civic medicine, to some extent at least. He also desires to extend his circle of influence, but often he does not know how to do it along public health lines. The newer activities of county medical societies include methods of extending the circles of influence of the societies through all the physicians and all the people in a community. # MEDICAL PROGRESS

The Action of Glycocoll on the Urticarial State—Professor K. Glaessner of Vienna has for many years taught that aminoacids are normally destroyed by the liver and that in damaged states of the latter they appear in the urine, from which he concludes that aminoacids serve as a means for measuring the efficiency of that organ. He used glycocoll for this purpose and found that it made the theory good. Later he made the further discovery that glycocoll may be useful as a "liver diuretic." In a special investigation of the phenomena of anaphylaxis he made a study of liver function and in following up this lead discovered accidentally that glycocoll antagonizes the urticarial habitus. The amount required is somewhat large—from 5 to 10 grams daily—but there are no ill by-effects which can be attributed to the drug. Given to a subject in the midst of an urticarial paroxysm in which the rash may be accompanied by fever, gastroenteric disorder, malaise, and other evidences of anaphylaxis, the symptom complex is seen to subside, the effect naturally being much more striking in the subacute and chronic types of case. Five case histories show that the patients developed urticaria from food factors only in a minority. In four of the five patients the antigen which caused the phenomena was not apparent. Irrespective of causation the drug brought about the desired result. We know of three types of anaphylactic phenomena which may at times overlap—the cutaneous (urticaria chiefly), the respiratory (asthma), and the gastroenteric, and whenever urticaria is a symptom glycocoll seems to act as a specific. On the other hand there was no response in isolated asthma and presumably none in the gastroenteric form with urticaria absent. The author frankly admits his inability to explain the favorable action, but hopes to do so after further investigation.—*Klumsche Wochenschrift*, March 26, 1927

Biochemical Studies of Skin Diseases—Stumpke and G. Soika contribute a second article on this subject, the first having appeared in 1924. Some of their conclusions are as follows. With kidneys intact there is evidence of nitrogen retention in many cases of eczema, acne, urticaria, and other dermatoses while hyperglycemia can be shown in half the eczematous patients studied. Calcium values in the blood were often disturbed, but might be increased or lowered. Disastase and lipase in the blood were usually normal in quantity but the

amount was disturbed in a minority. To explain these changes in the blood serum the authors invoke disturbance of either the endocrine glands or the vegetative nervous system. This factor is something quite distinct from that adduced by Jadassohn and Bloch, which has proved of value in practice, which involves the existence of special eczematogenous substances acting from without. The two factors, so far from excluding each other, can be readily harmonized. Metabolic anomalies, for example, may render the skin supersensitive to irritants. It has in fact been shown that certain blood anomalies render the skin more sensitive to the action of certain drugs. We know that in the clinic the subjects of frank anomalies of metabolism are predisposed to not one but many forms of dermatosis—the gouty, the diabetic, etc.—*Klumsche Wochenschrift*, April 2, 1927

The Treatment of Pernicious Anemia.—Henry C. Wales, writing in the *Journal of the Canadian Medical Association*, April, 1927, xvii, 4, relates his experience with the Minot and Murphy diet in a series of cases of pernicious anemia, including 12 patients in their first relapse, 17 in their second distinct relapse, and 16 who had had more than two relapses. These patients were on this diet for periods ranging from a few weeks to two and a half years. Five of the patients were seen only once, and of these three were improved. All of the others except three became rapidly better soon after taking the diet, and are still well. There was an improvement in the bowel movements, with a quick return from diarrhea to normally formed stools, an increased appetite, and an improvement in the blood picture—increase in the reticulated cells and red blood count. The icterus index of the blood serum early began to fall and in two to three weeks became normal. Within a month the yellow tint of the skin disappeared. As pernicious anemia is characterized normally by periods of remission, it is too early to say how long this improvement will be maintained. The Minot and Murphy diet consists of 120 to 240 gm of cooked beef liver or calves' liver daily (an equal part of lamb's kidney may be substituted occasionally), 120 to 240 gm of lean beef or mutton daily, 300 gm of vegetables, especially lettuce and spinach, 250 to 500 gm of fruit—peaches, apricots, strawberries, pineapple, or grapefruit, 40 gm of fat in the form of butter or cream, other fats and oils being excluded, one egg daily, two

glasses of milk and as much ordinary food as the patient wants. The only medication given is dilute hydrochloric acid, 1 to 4 c c half an hour before and during meals, the average amount being 15 c c daily.

**Heart Load**—Newton S. Stern, writing in the *Southern Medical Journal*, May, 1927, xx, 5, points out that the work the heart has to do depends upon five factors. These factors are blood pressure, stroke volume, the area of aortic orifice, duration of systole, and the heart rate. Though all of these factors are variable and some of them are difficult of measurement, if they can be combined in a formula they permit the calculation of the heart load in actual units of work. Stern has devised the formula,  $\left\{ R \frac{1.36 MP}{T} + \frac{M^3}{2A^2T^2} \right\}$

where R is the rate of the heart per minute, M is the stroke volume in c c, P is the blood pressure in mm Hg, T is the time in systole seconds, A is the area of the aortic orifice. The effect of the various factors is discussed with relation to the heart as a whole and to various pathological conditions. If other factors remain the same, though of course this is not always the case, the work of the heart is in direct proportion to its rate—the more rapid the pulse the greater the work the heart has to do. It can readily be seen, therefore, what a tremendous effect rest, morphine, and digitalis have on the heart simply by slowing its rate, as this increases the diastole, and allows more time for rest, recuperation, and nourishment of the myocardium. By substituting actual values in the formula the author shows that under basal conditions, the work the heart does may be expressed by 0.5 watt per minute, or 30 watts per hour. Under exertion the heart manifests a reserve power of 100 to 125 times the basal requirements. Under pathological conditions this reserve is encroached upon even in the basal state, by increase in the rate, the stroke volume, and the blood pressure, to say nothing of impairment of the muscle. This explains why heart patients show the same symptoms that develop normally after strenuous exercise.

**Purulent Pericarditis in Childhood**—Ernest G. Williamson reviews the literature of suppurative pericarditis, which shows that 117 cases of this condition have been recorded, and reports a case operated on at the Children's Hospital in Philadelphia by Henry P. Brown, Jr. The diagnosis is made by the history of recent infection, fever, usually septic in type, rapid pulse, dyspnea, restlessness, possibly cough, and precordial, epigastric, or abdominal pain. An x-ray examination is helpful. The treatment consists of incision and drainage. In the case reported, that of a boy seven years of age, there was a history of seven weeks illness, beginning with cervical adenitis and

followed by ptomaine poisoning, vomiting, and urticaria. An abscess formed in the left shoulder posteriorly. The parents were told that the child had pneumonia and nothing could be done for him. Shortly after admission the fluctuating tumor over the left scapula was incised, but no pus was obtained, and repeated punctures of the left chest failed to reveal pus. Finally, after x-ray examination, a diagnosis of serofibrinous pericarditis was made. Paracentesis pericardii was performed and seven or eight ounces of thin purulent fluid were removed, with quite marked relief of symptoms. Two days later the fifth costal cartilage and the adjacent portion of the sternum were resected, the mammary artery was ligated, the pleura reflected, and the pericardium incised. A large rubber drain was inserted. The patient's condition was grave for several days, but he finally improved. The sac was irrigated daily with warm saline solution until the twenty-fourth day, when, as fibrin seemed to be accumulating, Dakin's solution (20 c.c.) was employed. Under this treatment the fibrin and discharge decreased and the temperature showed a downward trend. Although a fistula persisted for a time, the child eventually made a perfect recovery. Williamson questions the advantage of the drainage tube. In most of the cases reported this was not used. Sufficient drainage is ordinarily provided by making an adequate opening in the pericardium and suturing its edges to the skin opening. The movements of the heart preclude the formation of pockets. The treatment of the infected pericardium is not sufficient in these cases, since it is likely that the myocardium is markedly diseased, as evidenced by palpitation, tumultuous heart action, dyspnea, tendency to syncope, cyanosis, and signs of heart failure. Dr. Brown's patient showed this condition in a marked degree and required frequentappings, and energetic medical treatment.—*Annals of Surgery*, May, 1927, lxxxv, 5.

**Primary Resection of the Stomach in Complete Perforation of Gastric or Duodenal Ulcer**—Professor Kreuter mentions the inevitableness of peritonitis after these accidents, to prevent which the source of infection should in theory be cut off. While we can establish formulae for the management of appendix-peritonitis and gall-bladder peritonitis, this is not the case with the peritonitis following perforated peptic ulcers. It is indeed conceded by all that the perforation must be closed but there are numerous differences of opinion as to the best method of procedure, largely because of the technical difficulties involved. To weigh all the evidence pro and con and then come to a conclusion will always remain a necessity. It is impossible even to allude to all of the individual procedures which have been recommended. The sole object of Kreuter's pa-

per has to do with the indications for resection. Those who do gastroenterostomy for unperforated ulcer will doubtless anastomose for perforation, and conversely those who have done many resections for ulcer will resect for perforations. A borderland exists in which either plan may give a good result, that is, the worst types of chronic ulcer may heal under simple anastomosis—but in the long run the surgeon who has become familiar with resection will prefer it in general and will even tend to employ it for perforation. For nearly five years the author has treated practically all cases of ordinary peptic ulcer by resection and has done 278 resection operations in that interval. The number of cases of perforation during this period was 62, and of these one-half were treated by resection, the rest being cared for by suture and anastomosis. The transition from palliative to radical has been gradual. The 31 cases treated by palliation gave 12 fatalities or 38.7 per cent mortality and those treated by resection showed but five deaths, or 16.2 per cent mortality.—*Klumsche Wochenschrift*, April 16, 1927.

**Röntgen Treatment of Ulcer of the Stomach and Duodenum**—Th. Barsony and L. von Freidrich, of Budapest, have tested this therapeutic resource on 75 patients with peptic ulcer. Apparently it does not go back further than 1923 and the authors first took it up in the following year and utilized it for a full year after which they ceased its employment until some sort of judgment could be passed on its efficacy. Matoni claims 77 per cent of actual cures after two and a half years, Schulze-Berge about 70 per cent after six months, and Lenz nearly 80 per cent of cures. The criteria for the use of röntgen therapy are positive Röntgen diagnosis and a clinical history of at least three years. None of the 75 cases reported in this article was submitted to the treatment until after medical treatment had failed—rest, Sippy diet, protein therapy. No other treatment was added to the radiation, the patients were not in bed and in fact went about their regular duties for the most part. The diet was light but not specific. The treatment consisted originally of a single session, but later of several sessions, mostly repeated at the end of a month. Of the 75 patients 65 were kept under observation for 1 to 2 years. The pains ceased in 30 of these only, and all but 2 of them returned sooner or later. At the close of 1½ years but two patients remained in good condition free from recurrence. The authors' results are therefore worse than any of those quoted above and the most that they can affirm is that the röntgen treatment may prove a good accessory to ordinary medical measures. Whether the other reporters used

medical treatment is not mentioned. The technique was very simple—half to one Holzknicht unit, 5 mm aluminum filter, and distance 30 cm. The duration is not stated.—*Klumsche Wochenschrift*, May 7, 1927.

**Pituitary Extract in Gallstone Disease**—Professor C. Garré has sought to determine whether this treatment will prove a rival to ordinary surgical intervention. There is evidence that injections of hypophysin can empty the gallbladder and force the expulsion of small stones. The same claim has been made with conflicting results in the case of kidney stone. The operating surgeon has the best chance of convincing himself on this score for after the drug has been injected he can actually watch the gallbladder directly. From the theoretical standpoint something like 90 per cent of gallbladders which come to operation show diseased walls—from simple inflammatory edema to more or less cicatricial alteration, and it is extremely doubtful if these altered walls retain the power of contractibility or could respond to injections of the drug. These walls are moreover apt to be infected even when the bile is sterile and it might readily happen that old infectious foci would become mobilized. In regard to the ability to expel small stones from the gallbladder this might happen conceivably if the stone chanced to be present in a so-called stasis gallbladder with hypotonia of the muscle, the latter being able to respond to stimuli through the parasympathetic nervous system. In all other conditions, including chronic cholecystitis, hydrops, and empyema, the drug would not be able to expel stones from the gallbladder because of several factors, one of which is reflex closure of the sphincter of Oddi as soon as the stone enters the cystic duct and another the probable inability of the muscle to respond to stimulation. The author has often tested the expulsive treatment with negative results. He apparently prefers atropine and warmth to relax sphincteric action and some of the newer cholagogues, with the addition of salines to promote duodenal peristalsis and increase and promote the flow of bile, although he does not regard these as rivals to operative surgery.—*Deutsche medizinische Wochenschrift*, April 22, 1927.

**Alcohol Abuse and the Liver**—Professor G. von Bergmann refers to the report of Eppinger, of Vienna covering 319 cases of hepatic cirrhosis, of which but 24 per cent were examples of typical Laennecatrophic cirrhosis and 64 per cent of the hypertrophic form. This leaves 70 per cent of mixed and atypical cirrhosis. Of victims of atrophic cirrhosis 61

per cent confessed to the abuse of alcohol, while in the hypertrophic form the same percentage was 26. Taking up the entire 319 cases, 14 per cent of the men and 58 per cent of the women had never used alcohol and many more were evidently only moderate users of it. The author attacks the problem of the relation of alcohol to the liver from another angle and seeks to show that even transient overindulgence notably affects the functions of the organ. He has studied from this angle 105 individuals, of whom 71 had some affection of the liver while 34 were normal so far as hepatic function was concerned. The substance used for testing hepatic efficiency was bilirubin given by intravenous injection and the content of the blood serum and urine was determined later after having made sure that the urine was previously free from the coloring matter of the test. Hepatic insufficiency is naturally shown by retention and delayed elimination. In 7 cases of actual cirrhosis slow elimination was invariably found, although much more marked in some cases than in others. In addition, in chronic alcoholics without cirrhosis a study of 26 cases showed distinct retention in 5 and marked retention in the same number, while 6 showed a mean normal figure and 10 the upper limit of the average. In eleven cases in which there was no chronic abuse, but transitory acute alcoholism, 3 showed slight retention and 2 marked retention. The author contends that he has shown the power of alcohol to influence unfavorably the hepatic functions, so that in the chronic abuser with defective elimination of injected bilirubin we may speak of a latent cirrhosis.—*Klinsche Wochenschrift*, April 23, 1927.

**Insulin in Diabetic Retinitis** — L. Genet relates five case histories of the influence of insulin treatment of diabetes on the retinitis which develops in that affection. In but two cases was there seen an amelioration in the acuity of vision and this was but slight. In the other three not only was there no favorable influence exerted, but the complication went from bad to worse. A study of the favorable cases ought to throw some light on the failure of the treatment in the others. That the slight improvement was due to the insulin may be doubted, for in one case an iritis had been present with involvement of the vitreous, and the improvement could have been explained by the spontaneous clearing up of the latter. As a matter of fact there was no change seen in the fundus which could account for the improved vision. In the other favorable case there was nothing to explain the slight benefit and nothing to show that the fundus had undergone any objective alteration. At least from the objective standpoint there is no rea-

son to believe that insulin can produce any favorable alteration in the fundus in true diabetic retinitis. The author refers, however, to favorable reports from other ophthalmologists, which indeed offered the occasion of his making a special study of the subject. The fact that one patient did obtain some subjective improvement which could not be explained in any other way leaves the subject still open, but it is evident that future alleged cases of improvement will have to be carefully documented. There are sources of fallacy to be considered, for example in connection with hemorrhagic types of retinitis which are known to improve spontaneously.—*Journal de médecine de Lyon*, March 20, 1927.

**Cranial Traumatism causing Alterations of the Hypophysis** — A. Galluppi sums up his study of this subject by stating that cranial injuries are very often responsible for setting up hypophyseal syndromes. That the relation of cause and effect is not more frequently established is due to inadvertence and because of the complex symptomatology of cranial injuries. Hemorrhages within and outside the hypophysis are often overlooked. They are often absorbed without sequelae or the cysts formed are too small or there is a resulting scleroatrophy of the organ. The volume of the sella is often diminished because the free osseous appendages are readily deflected by cranial injury, and hyperostoses and synostoses sometimes result. Anomalies of the internal secretions of the hypophysis may be masked by participation of other endocrines. When the hypophyseal symptoms appear the patient may have already recovered from his cranial traumatism. In the youthful subject with partial arrest of development, moral deviations, instability, etc., it is well to consider the possibility of a traumatic origin acting through the hypophysis. Three cases are narrated. In one a man of 36 sustained a trauma in the occiput. The clinical picture was vague, but examination of the visual fields with radiography of the sella pointed to the hypophysis as the source of the symptoms. In the second case in a young man of 21 there had been an injury of the cranium at the age of 4 years. The radiographic diagnosis of very small sella was confirmed by autopsy. This with the limited vision and visual fields reduced one half were sufficient for a diagnosis. Other typical symptoms were headache, diabetes insipidus, etc. The third patient, a woman of 44 had received a cranial injury at the age of 10. Both this and the preceding patient showed arrest of skeletomuscular development. The sella and visual fields were characteristic in this patient.—*Revue Française d'Endocrinologie*, February, 1927.

# LEGAL

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York.

## SUPREME COURT OF THE UNITED STATES UPHOLDS THE VIRGINIA STATUTE PROVIDING FOR THE STERILIZATION OF MENTAL DEFECTIVES

The recent decision of the Supreme Court of the United States in the case of *Buck vs Bell* upholding the Virginia statute providing for the sterilization of mental defectives under careful safeguards, should arouse interest not among physicians only, but with all persons who are interested in the problems of eugenics and the betterment of the race. It should be of special interest to the citizens of New York State where a similar statute a few years ago was declared unconstitutional, and then repealed.

In 1912, Article 19 was added to the Public Health Law of our State. It provided for a board of examiners of the feeble-minded, criminals and other defectives, and made it the duty of that board to examine into the mental and physical condition and the record and family history of the feeble-minded, epileptic, criminal and other defective inmates confined in the several state hospitals for the insane, state prisons, reformatories and charitable and penal institutions. The statute provided that if in the judgment of the majority of the board, procreation by any person would produce children with an inherited tendency to crime, insanity, feeble-mindedness, idiocy or imbecility, and there was no probability that the condition of any such person so examined would improve to such an extent as to render procreation by any such person advisable, or if the physical or mental condition of any such person would be substantially improved by an operation for the prevention of procreation, then and in such case the board should appoint one of its members to perform such an operation as should be decided by the board to be most effective for that purpose. The criminals who came within the operation of that law were those who had been convicted of the crime of rape or of such a succession of offenses against the criminal law as in the opinion of the board should be deemed sufficient evidence of confirmed criminal tendencies.

Under the New York statute, an elaborate machinery was provided for the protection of the person upon whom the operation was to be performed. It compelled the board of examiners to apply to a judge for the appointment of counsel to represent the person to be examined, and that all orders entered in such proceedings were subject on appeal to a stay. After such an

order was made and decided on appeal, the board of examiners was required to preserve in the institution where the inmate was confined the record of the proceeding, and the superintendent of the institution was compelled to report to the board of examiners at the conclusion of one year "the condition of the inmate and the effect of such operation upon such inmate."

The statute further provided that "Except as authorized by this act, every person who shall perform, encourage, assist in or otherwise permit the performance of the operation for the purpose of destroying the power to procreate the human species or any person who shall knowingly permit such operation to be performed upon such person unless the same shall be a medical necessity, shall be guilty of a misdemeanor."

This statute marked an advance in endeavoring to make practical application of the principles of eugenics to the end that society might take proper measures to bring about a better race.

In regard to a similar statute in California, the Attorney General of that state declared, "I am of the opinion that these are grave constitutional questions," but "as restricted to the sterilization of the inmates of prisons and hospitals by the method of vasectomy, I am of the opinion that there are no legal inhibitions upon this enlightened piece of legislation which is an awakening note to a new era and a great advance toward that day when man's inhumanity to man will have acquired a meaning beyond mere frothy sentiment."

In the State of New Jersey, a similar statute came before the Courts, and in a decision written by Judge Garrison (Secretary of War under the Wilson administration), the New Jersey statute was declared unconstitutional.

The New York statute came before our Courts in 1918 in the case of *Osborn vs Thomson*. In that case, Frank Osborn was an inmate of the Rome Custodial Asylum, twenty-two years of age, strong physically but feeble-minded. The board of examiners provided by the statute determined to perform on Osborn the operation known as vasectomy, and Osborn through his counsel, sought an injunction from the Court preventing the operation. The case came on in March, 1918, before Mr. Justice Rudd.

Much medical testimony was taken, most of

which was against the performance of the operation. The constitutionality of the statute was attacked, the claim especially being that the same was in violation of the Fourteenth Amendment of the United States Constitution which declares "that no state shall deny to any person within its jurisdiction the equal protection of the laws."

In a twelve page opinion, Mr Justice Rudd reached the conclusion that the statute was unconstitutional, and that by reason of the same Osborn was not given the equal protection of the laws. The judgment in the Osborn case was appealed to the Appellate Division where by unanimous decision it was affirmed without opinion. Because of this, no doubt, in 1920, the New York statute was repealed.

The testimony of the physicians who gave evidence in the Osborn case may be thus summarized.

Dr Lemon Thomson, one of the board of examiners, testified that the board had selected Osborn after learning as to his family and after submitting him to a somewhat superficial examination physically and mentally, and that such selection was made because in the opinion of the commission Osborn could not probably procreate normal offspring. His was what the board of examiners thought a bad case. Dr Thomson further testified that he had never performed the operation of vasectomy for sterilization, that in his opinion no benefit would come to the patient from the operation so far as rendering him free from the dangers of the infection of a venereal disease, and that the operation would not weaken in Osborn the tendency of a rapist.

Dr Andrews, another member of the board of examiners, testified before Mr Justice Rudd that he had never performed the operation, that he had never seen it performed, and that while the statute required the board to determine upon such operation as would be most effective, he believed that vasectomy would not be the most successful operation, but on the other hand, castration would be.

Dr Bernstein, the superintendent of the Rome Custodial Asylum where Osborn had been confined as an inmate since 1907, and in which more than 1,300 patients were cared for, testified that Osborn was of a higher grade of feeble-mindedness, that the actual number of feeble-minded in New York State had not increased proportionately in twenty-five years, that because of the demands of society there developed many social failures, that there had been a persistent demand for the removal of such individuals from temptations in the community, and that these social failures were forced upon the attention of the state so that it had become an accepted principle that the state must care for its defectives. Dr Bernstein further swore that he had

observed 5,000 feeble-minded patients, that Osborn could not earn his living outside of the institution if he were turned out into the world that he had an eight-year mental capacity, that all patients in the institution are segregated, and upon the question of Osborn being able to procreate normal children he said, "We are taught that the dominant traits appear in three quarters of the offspring and recessive traits appear in one-quarter, when the parentage is mixed as regards traits, that it is only in cases of feeble-mindedness of both parents that you would look generally for an increase of feeble-mindedness among offspring."

Dr Bernstein further swore that vasectomy would not change any of the criminal tendencies of the feeble-minded and would only eliminate the one element of procreation, and that in his opinion one of the conditions which would result from a general enforcement of the law would be the tendency to create a class of people who would feel that they were so abnormal that they could indulge in promiscuous sexual relations, and that there would be known places where these people would be harbored, and there they would tend to collect. Further he said that among persons who had been sterilized, you would find increased sexual intercourse, and that such illicit intercourse is a promoter of disease and general demoralization.

It was Dr Bernstein's sworn opinion that the proposed operation on Osborn should not be performed as it would not help him or any of the other 1,300 inmates of the institution or society in general, that were the operation performed, Osborn would nevertheless require supervision and care, and that after the operation, his natural desire would be just as great to seek female companionship. Further, that in his judgment, society needs protection from the raping of little girls and the frightening of them just as much as it wants protection from a future generation of dependents and delinquents. It was the doctor's opinion that the legislation in question was "in advance of our enlightenment," as at that time the subject was not sufficiently understood. He believed that a careful and scientific study of ductless glands and their secretions shows that when such secretions forming in the body are interfered with, conditions are created which affect the brain and the nervous system.

Dr Davenport, a biologist, testified that he agreed with Dr Sharp's article on "Vasectomy as a Means of Preventing Procreation in Defectives," in which article it was stated that "defective persons are not necessarily to become a public charge, for included within this class are to be found the most gifted as well as the most vicious, weakest and ordinarily the most unhappy of mankind," mentioning Chatterton, Goldsmith, Coleridge and Charles Lamb as instances. Dr

Davenport said that he did not advocate the operation of vasectomy, believing segregation of the sexes was preferable

Dr Coakley, a specialist in vivisection, testified as to the danger of infection because of the retained secretions in the body, that in the operation the vas deferens is severed, but that it can be reunited even after considerable length of time, and that therefore nothing would be accomplished by such an operation

Dr Fernald, superintendent of the School for Feeble-Minded in Massachusetts, testified that he had never seen an authorized medical statement based upon actual facts which would justify claims made for the results in Indiana, where such a law is in operation, that the operation of vasectomy does not in the slightest interfere with the physical act of sexual intercourse, that illicit intercourse would result, and that the effect thereof would be the exchanging of the burden of feeble-mindedness for the burden of sex immorality or sex diseases and of insanity resulting in that condition which would be quite as serious and would affect people who are producers and burden bearers Dr Fernald believed that the operation would prejudice many right-thinking persons against institutions for the feeble-minded when it became known that under the law such an operation could be performed against the wishes of the inmate

The medical testimony thus marshalled before Mr Justice Rudd was not contradicted, and it was natural enough therefore that the Judge should accept this uncontradicted evidence and should follow it No doubt, other and equally impressive testimony could have been marshalled on the other side which might have given the matter a different aspect, but no such testimony was produced While a decision in the Osborn case was primarily based upon the conclusion that the New York statute was unconstitutional, from our studies of the nature of judicial process, we can not but wonder whether the decision would have been otherwise had medical testimony of a different character been presented to the Judge

In May of this year, the question of the constitutionality of the Virginia statute similar in all of its essential details to that of the New York statute, came before the United States Supreme Court, and its constitutionality was upheld

The Virginia statute recites "that the health of the patient and the welfare of society may be promoted in certain cases by the sterilization of mental defectives, under proper safeguard, that the sterilization may be effected in males by vasectomy and in females by salpingectomy, without serious pain or substantial danger to life, that the Commonwealth was supporting in various institutions many defective persons

who if now discharged would become a menace but if incapable of procreating might be discharged with safety and become self-supporting with benefit to themselves and to society, and that experience has shown that heredity plays an important part in the transmission of insanity, imbecility, etc"

The statute then provides that whenever the superintendent of certain institutions for epileptic and feeble-minded persons should be of the opinion that it is for the best interests of the patient and of society that an inmate under his care should be sexually sterilized, he may have the operation performed upon any patient afflicted with hereditary forms of insanity, imbecility, etc., on complying with the very careful provisions by which the act protects the patient from possible abuse

The procedure provided by the Virginia statute is very similar to that of the repealed New York law

The Supreme Court made short work of the attack upon the constitutionality of this statute, and in an opinion of great brevity but extreme clarity, Mr Justice Holmes, the distinguished son of the distinguished physician, Oliver Wendell Holmes, outlined the reasons why the Virginia law should be upheld

"The attack is not upon the procedure but upon the substantive law," declared Mr Justice Holmes "It seems to be contended that in no circumstances could such an order be justified It certainly is contended that the order can not be justified upon the existing grounds The judgment finds the facts that have been recited and that Carrie Buck 'is the probable potential parent of socially inadequate offspring, likewise afflicted, that she may be sexually sterilized without detriment to her general health and that her welfare and that of society will be promoted by her sterilization,' and thereupon makes the order In view of the general declarations of the legislature and the specific findings of the Court obviously we cannot say as a matter of law that the grounds do not exist, and if they exist they justify the result We have seen more than once that the public welfare may call upon the best citizens for their lives It would be strange if it could not call upon those who already sap the strength of the state for these lesser sacrifices, often not felt to be such by those concerned, in order to prevent our being swamped with incompetence It is better for all the world, if instead of waiting to execute degenerate offspring for crime, or to let them starve for their imbecility, society can prevent those who are manifestly unfit from continuing their kind The principle that sustains compulsory vaccination is broad enough to cover cutting the fallopian tubes *Jacobson v Massachusetts*, 197 U S 11 Three generations of imbeciles are enough"

In the New York case, Mr Justice Rudd, in explaining the reasons for his conclusion that the feeble-minded Osborn was not given the equal protection of the law guaranteed by the Constitution, declared "He is no different from many others, running no doubt into the thousands in our state who are not within the confines of a state institution, and who taken together with those who are in institutions and similarly situated, mentally and physically, make up a large class of mentally deficient people. Can it be said that the law can direct the physical mutilation of the bodies of those who are in the state's care, and not be concerned with the same class of persons who are in the world at large?"

A similar contention was made in regard to the Virginia statute, but Mr Justice Holmes made short work of that contention in these words, "But, it is said, however it might be if this reasoning were applied generally, it fails when it is confined to the small number who are in the institutions named and is not applied to the multitudes outside. It is the usual last resort of constitutional arguments to point out shortcomings of this sort. But the answer is that the law does all that is needed when it does all that it can, indicates a policy, applies it to all within the lines, and seeks to bring within the lines all similarly situated so far and so fast as its means allow. Of course, so far as the operations enable those who otherwise must be kept confined to be returned to the world, and thus open the asylum to others, the equality aimed at will be more nearly reached."

The decision of the Supreme Court of the United States in the Virginia case should prove of vital interest to every physician in this country. Whether or not in the trial of that case there was expert testimony, does not appear from the opinion of the United States Supreme Court,

but in any event, the highest tribunal of the land has now determined once and for all time that society has the right to protect itself against the procreation of those who will become a burden and a public charge.

Who is there that would attempt to answer these unanswerable assertions of the Supreme Court of the United States? "We have seen more than once that the public welfare may call upon the best citizens for their lives. It would be strange if it could not call upon those who already sap the strength of the state for these lesser sacrifices, not often felt to be such by those concerned, in order to prevent our being swamped with incompetence. It is better for all the world, if instead of waiting to execute degenerate offspring for crime, or to let them starve for their imbecility, society can prevent those who are manifestly unfit from continuing their kind?"

With our recent crime waves and the overcrowding of the Courts to such an extent that justice is notoriously delayed if not denied, may it not be our duty here in New York State, at least to consider whether or not the statute which we repealed in 1920 should now be re-enacted?

The plaintiff, Carrie Buck, in the United States Supreme Court case was a feeble-minded, white woman who was the daughter of a feeble-minded mother of the same institution, and herself the mother of an illegitimate, feeble-minded child. If the state has not power over its citizens sufficient to enable it to curtail the menace involved in the procreating powers of such a person—a curtailment which involves no deprivation either of life, liberty or happiness—by what reasoning can it claim the right, should another war descend upon us, to demand the life of such a man as Charles A. Lindbergh?

## REMOVAL OF MIDDLE TURBINATE AND POLYPS FOLLOWED BY MENINGITIS AND DEATH

An administrator instituted an action against a physician specializing in nose and throat work, seeking to recover damages for the death of his intestate, which was claimed to have been due to the defendant's negligence in operating upon the deceased.

The complaint charged that the defendant physician had advised the deceased that it was desirable and necessary to perform an operation upon him for the removal of a few polyps and part of the middle turbinate and of the ethmoid bone, and that such operation was performed by the defendant upon the decedent, that by reason of the negligence and

improper conduct of the defendant in the performance of his operation the deceased became infected, from which infection he contracted meningitis and died ten days after the performance of the operation.

The deceased was a man of about 62 years of age and conducted an optical store in the neighborhood of the defendant's office. For a long time he had been affected with ethmoiditis, and several years prior to this operation the defendant physician had removed several polyps from the decedent. Shortly prior to the operation, the deceased called on the defendant complaining of headaches and

difficulty in breathing. Upon examination the physician found that the nasal sinuses were obstructed by several polyps, and advised the removal of them and of the posterior portion of the middle turbinate. The anterior portion had been removed several years previous.

The operation was consented to, and under a local anaesthesia of cocaine and adrenalin the defendant proceeded to the removal of the posterior portion of the middle turbinate and snared out several polyps with a wire snare. The instruments used by the defendant in this operation were proper and had been carefully sterilized before using. Upon completion of the operation the patient rested at the physician's office for a few hours and then left for his home. The operative field had been packed with iodoform gauze dipped in a 2% solution of mercurochrome. On the day following the operation, the patient returned to the defendant physician, the packing was removed and the parts cleansed and irrigated with Dobell's solution. At this time there was nothing untoward in the appearance of the patient. On the second day following the operation the physician was called to the patient's home, where he found him to have a fever, with a temperature ranging from  $101^{\circ}$  to  $102\frac{1}{2}^{\circ}$ . He prescribed aspirin and phenacetin and the application of ice bags to the head. On the next day he again visited the patient at his home, at which time the temperature was slightly higher. After this visit an internal medicine man was called in consultation, and after examination he advised the performance of a lumbar puncture, which was done by a pathologist. About 4 o'clock in the afternoon of this day, the third day after the operation, the patient was removed to the hospital where a second spinal puncture was per-

formed and a pathological examination disclosed that the patient was suffering from meningitis. He was given about four doses of anti-streptococcus serum, one dose every six hours intraspinally. The patient did not respond to this treatment, grew continuously worse, went into a coma and died early in the morning of the fourth day after the operation. The cause of death was given as septic meningitis (non traumatic) following ethmoiditis, contributory cause cardiac failure.

There was no fracture of the cribriform plate and the defendant physician felt that the meningitis was most probably due to a lighting up of the chronic infection present in the ethmoid cells. He also felt that the old infection from which this patient suffered for many years extended into the meninges through the nerve sheaths in the openings of the cribriform plate, likewise, that it was possible that the meningitis might have occurred without any operation having been performed upon the patient.

For several years the administrator continuously prosecuted the action and examined the defendant physician before trial, in preparation of the presentation of his case. He then became lax in the prosecution and sought to procure a settlement, first for a large sum and finally for his hospital and funeral expenses.

Fully believing that the patient's death was not due to any negligence upon the part of the defendant, all offers of compromise were declined.

The time having passed when the action should have been brought on for trial and disposed of, a motion was made on defendant's behalf to dismiss the case for lack of prosecution. The motion was granted, thus terminating the case in defendant's favor.

# NEWS NOTES

## COMMITTEE ON PUBLIC RELATIONS

The Committee on Public Relations of the Medical Society of the State of New York met on Friday morning, June 17, 1927, in Room No. 46 of the Academy of Medicine, New York City. The following were present: Dr. Fisher, chairman, Dr. Mitchell, Dr. Sadher, Dr. Trick, Dr. Farmer, and Dr. Lawrence. Dr. Fisher announced that Dr. Morris had been excused.

The first order of business was a consideration of the duties and function of a County Society Public Relations Committee, and the following five points were adopted:

1. Make a complete survey of health agencies in the county, noting the names, membership, program, and manner of carrying on same.

2. Collect data concerning all types of medical activities, both curative and preventive, and whether promoted by official or unofficial agencies.

3. Confer with director or proper committee of every agency or organization interested in conducting or promoting curative and preventive medical activities in the county, with regard to its program, for the purpose of offering assistance in the development of the medical phase of such program.

4. Confer frequently with the public health committee of the County Society regarding the methods employed in public health work throughout the county.

5. Be prepared to take the leadership in developing medical programs of county agencies.

The Committee was of the opinion that it might be difficult at times to separate the function of a public health committee and a

public relations committee, and that the smaller Societies may find it desirable to have the same personnel function as both committees. But, where possible, it was agreed that there should be two separate committees.

The second matter discussed by the Committee was the subject of future conferences with State health agencies, and it was decided that a conference should be sought with representatives of the following, at an early date after the vacation period: State Department of Health, State Department of Education, State Department of Mental Hygiene, Red Cross, and the Association for the Prevention of Cancer.

Another subject for future consideration of the Committee is the development of a liaison with lay groups, with the idea of bringing before the public a comparison of the work done by private physicians and public agencies, for the purpose of keeping the public intelligently informed as to the quantity and character of service rendered by the private physician. It was felt that at present all medical publicity features are too exclusively the activities of public officials, whether physicians or nurses. It was realized that this is a perfectly natural development, but it was felt that the public is, unfortunately, being misled, in that so little comment has been made of the assistance rendered by the private physician. The Committee realized that this is a difficult problem, and the activity along this line would readily admit of being classified as stimulated by a jealous motive.

There being no further business, the Committee adjourned until 2:00 P. M., when it will meet in conference with representatives of the State Charities Aid Association.

---

## THE JOINT COMMITTEE ON PUBLIC RELATIONS

The Joint Committee on Public Relations met at two o'clock, June 17, 1927, in the New York Academy of Medicine. Those present were:

From the State Charities Aid Association: Mr. Homer Folks, Dr. Farrand, Dr. Weiskotten, Dr. Burnham, Mr. Nelbach and Mr. Kingsbury.

From the State Medical Society: Dr. Fisher, Dr. Mitchell, Dr. Sadher, Dr. Trick, and Dr. Lawrence.

Dr. Fisher presided. He stated that the report of the Joint Committee, which was submitted by the chairman, Dr. Cottis, to the House of Delegates and which was published in the June 1 issue of the New York State Journal of Medicine, was received with favor everywhere and he had heard none but favorable comments upon it.

Mr. Folks stated that the report was favorably received, and was adopted by the State Charities Aid Association, and only favorable

comments had been received from members of County Committees who had seen it. He stated that it is the intention of his Association to publish the report in the State Charities Aid Association News in an early issue. This publication has a circulation of 24,000. The report will be accompanied by a comment prepared by Mr Folks. In addition to that, a letter will be sent to each County Public Health Committee calling attention to the details of the report, and the Association's field agents will be instructed to help every County Committee frame its program in accordance with the spirit of this report.

The Committee then considered the duties of a Committee on Public Relations of a County Medical Society, as outlined at the morning conference. The outline met with general approval, and Mr Folks stated that the State Charities Aid Association will prepare a similar program for the County Committees, and publish it at about the same time with that of the State Society, in order to prevent any confusion that might arise from the lack of information.

A discussion followed on the efforts that are being made at present toward the erection of county health units. Mr Folks announced that, as he understood it, the procedure should be that the County Medical Society would take the initiative in bringing the matter before the board of supervisors, that the Committee on Tuberculosis and Public Health should assist and support the Medical Society by creating public opinion in favor of the move.

The County Medical Society will also invite to its assistance representatives of the State

Department of Health. It is thought that these three organizations should limit their activity during the next year to five or six selected counties.

Mr Folks further suggested that a working committee, similar to the Anti-Diphtheria Working Committee, be appointed from the three agencies named above, for the selection of the counties and development of a program. Such committee should begin to function as early as possible in order that the proper budgets may be prepared and be ready for submission to the boards of supervisors when they meet early in November.

It was also realized that the sponsors of the county health unit will have a great responsibility for the future success of all attempts at organization and, therefore, great care should be exercised in the selection of the county and the details of the program.

The Committee then considered the manner of developing the county programs, providing for proper cooperation and publicity. It was agreed that special efforts should be made to give the private physician his share in all publicity. Mr Folks, on the part of his organization, said that he knew the local units would be glad to cooperate. He and others realized that it is highly desirable that information of the part played by the physicians be given to the public and that voluntary agencies should function as the selling agents for reputable and proper medical care, as opposed to quacks and cults. Publicity will necessarily differ with the problem and the community.

### LECTURES TO COLORED PHYSICIANS

A post-graduate medical course for colored physicians is being given in the Tuberculosis Division of Bellevue Hospital weekly. This course started June 15th, from 2 to 4 p m, under the auspices of the New York Tuberculosis and Health Association.

The program of lectures is as follows:

June 15—The History of Tuberculosis. Motion Picture "Peter Meets a Menace."

*Dr Iago Galdston*

June 22—Physical Diagnosis. A talk on percussion and auscultation, with clinical material to bring out the important points in each subject.

*Dr George G Ornstem*

June 29—A clinical lecture to demonstrate the importance of history taking.

*Dr Foster Murray*

July 6—The Importance of Physical Findings in the Diagnosis of Pulmonary Tuberculosis.

*Dr Grant Thorburn*

July 13—The Various Forms of Pulmonary Tuberculosis.

*Dr James Alexander Miller*

July 20—The Complications of Pulmonary Tuberculosis.

*Dr Edward P Eglee*

July 27—The Prognosis of Pulmonary Tuberculosis.

*Dr Catherine R Kelley*

Aug 3—Treatment of Pulmonary Tuberculosis.

*Dr George G Ornstem*

## THE HEALTH OFFICERS CONFERENCE

The annual conference of the Health Officers of New York State was held in Saratoga Springs on June 28-30, 1927. This conference is official, being provided for by the Public Health Law of New York State. About eight hundred physicians were in attendance, nearly all of whom lived in the Grand Union Hotel as has been the usual custom during recent years. There are obvious advantages in all those in attendance living and dining together, and few places besides Saratoga Springs can offer these advantages. About one-quarter of all physicians outside of the cities of New York State are health officers engaged in the practice of public health and civic medicine, and nearly all are active members of County Medical Societies. The conference may therefore be considered as the annual gathering of the rural physicians. It may also be considered as the section on Public Health of the State Medical Society.

The conference also included the Public Health nurses, who were present to the number of six hundred or more. While the nurses sometimes met in their own sections, they also attended the general sessions. One great advantage of the conference was that of meeting one's colleagues and discussing mutual problems informally while sitting on the cool verandas. The inspiration gained from an exchange of ideas goes far toward maintaining the morale of the health officers. In fact, some health officers say that they continue to serve their communities in order that they may meet their fellows in the annual conventions. The conferences are concrete demonstrations of the deep interest which family doctors take in the practice of public health and civic medicine.

The conference was opened by Dr. Matthias Nicoll, Jr., Commissioner of Health, who gave an informal review of the problems which are now before the State Department of Health. He said that all of these problems could be handled by the local committees more efficiently than by the State Department of Health. The local communities would provide the machinery for doing so. The machinery which is suggested is a county board of health, which has been provided by the Statute Law in existence for over six years. Dr. Nicoll said that a practical budget for a county health department would be from \$15,000 to \$25,000 a year, one-half of which would be paid by the state. The present health officers would be retained as deputies of the county, and would perform practically the same work that they are now doing. In addition the county health officer and Board of Health would perform the higher duties which the local boards of health cannot perform on account of the lack of funds and the field of work. Dr. Nicoll hoped that a few counties would adopt the plan this year and he promised the assistance of the State Department of Health in starting the work.

The Health Officers Association which is a voluntary association with its own officers, debated the county health officer principle and adopted a sweeping approval of the plans.

The plan of a county health officer has been approved by the Medical Society of the State of New York and has been adopted as one of the objects to be accomplished by the Public Relations Committee.

Dr. Edward McKernon, Superintendent, Eastern Division, Associated Press, New York City, told the health officers how they could secure newspaper publicity. He said that in order to obtain publicity, the health officer must make use of something which is of interest to the people. Items of scientific matter and social progress are not news unless exceptional. To say of a prominent man who is sick that his temperature is 100, pulse 90, respiration 18, is dull news. But it would be news for the doctors to say that the sick man woke up at midnight and asked for a ham sandwich.

The speaker advised the health officer to be on friendly terms with reporters and editors, and to make reporters welcome in their offices. The medical profession was not sufficiently confidential with reporters, but the reporters would always refrain from publishing news which was given them in confidence. The better understanding between doctors and reporters will be of immense value in the cause of public health. Mr. McKernon especially dwelt on the necessity of giving news concerning hospitals, especially regarding their course, number of patients, expenses of hospitals, and plans for enlargement. This need not necessarily be an advertising of the local doctors, but it will be of great aid in promoting a knowledge of the hospital among the people. He also said that the public health was not merely a duty, but it was also a business. If a community cannot afford to have both a mayor and a health officer it should have a health officer. The public is not looking for more rights, but for more freedom from disease and for greater comfort and happiness.

Dr. James E. Sadler, President of the Medical Society of the State of New York, occupied a prominent place on the program. He spoke of curative medicine in contrast to preventive medicine. He said that curative recognized only the individual, while the preventive is of public importance. The thousand and more health officers of New York State are a great army engaged in public health—an army larger than most doctors realize. The health officers have the opportunity to advise a community in public health and civic medicine and so regain the place which was held by the medical profession in the days of our grandfathers.

Dr. Sadler described the work of the Public Relations Committee and outlined its work in

bringing about cooperation between the trinity of organizations—the family doctors, the boards of health, and lay organizations, and he commended the work of some of the county societies in assuming the leadership in all public health matters

Dr Veranus A. Moore, Dean of the New York State Veterinary College, Cornell University, Ithaca, described the prevention of rabies in New York State and the methods for preventing its spread

Dr Sanger Brown, 2nd, Assistant Commis-

sioner, State Department of Mental Hygiene, described the work of preventing mental derangements among the school children

Dr William H. Park, Research Laboratories, New York City Department of Health, described the prevention and treatment of scarlet fever

These are examples of the kind of subjects which were discussed at the conference from a practical, rather than a theoretical point of view

This conference was one of the most interesting and constructive that has ever been held

## BRONX COUNTY MEDICAL SOCIETY

A regular meeting of the Bronx County Medical Society, held at Concourse Plaza, on May 18, 1927, was called to order at 9 P. M., the President, Dr. Friedman, in the Chair

Election of candidates being in order, it was moved and carried that the Secretary be instructed to cast one ballot for the following membership

The following eleven doctors were elected to membership: Julius B. Bailen, Julius J. Carucci, Harry J. Cohen, Raphael d'Isernia, Samuel M. Friedland, Barney Lifshay, H. Peter Maue, Judah Minkin, Joshua Schwartz, Schmerl I. Seidenberg, Herbert S. Weichsel

Dr. Boas, for the Committee on Public Health and Medical Education, reported on the pamphlet advocating periodic health examinations, published under the auspices of the Bronx County Medical Society. The pamphlet is now ready, the cost of printing and distributing same being defrayed by the Bronx Tuberculosis and Health Committee, which has a large supply on hand and will gladly send them to any physician who requests them or mail them directly to the physician's patients

Dr. Boas also reported that articles have been prepared by a section of the Committee, under Dr. Biloon, particularly on the subject of diphtheria immunization, and arrangements have been made for these articles appearing in the *Bronx Home News* at weekly intervals. The report also dealt with the addresses, motion pictures and radio talks presented on the subject of periodic health examinations

Dr. Lukin, for the Committee on Medical Economics, reported progress

The Treasurer, Dr. Keller, emphasized the necessity of the members securing more ads for *The Bulletin*. He appealed to the members for further cooperation

A report of the Building Committee was received, stating that the building of the Professional Office Building has been resumed, a new Company is responsible for its erection, and it is not known as yet as to whether we can carry out the original contract. Our Counsel will be

asked to confer with our Building Committee and representatives of the Professional Office Building

A report was received from Dr. Weitzner, Chairman of the Social Committee, regarding the problem of the Society group for tennis players

Dr. Henry Roth, for the Relief Committee, presented the general rules and suggestions adopted by the Committee and appealed to the members for further co-operation

Dr. Friedman reported for the Committee appointed by the Mayor to take up the question of the reorganization of the Health Department as suggested by the Commissioner of Health. It was moved and carried that inasmuch as this proposal comes from the Commissioner of Health and inasmuch as it is apparently the aim of the Department of Health to keep pace with the needs of the Department, the Bronx County Medical Society go on record as approving the reorganization plan

Dr. Gitlow proposed the following Amendments to the By-Laws of the Society

Amend Section 11 (Standing Committee) by adding "and a Relief Committee consisting of seven members,—the President, Secretary and Treasurer of the Society and four other members"

Add—Section 82 (a)—

### "RELIEF FUND AND RELIEF COMMITTEE

- "(a) The Society shall maintain a Relief Fund
- "(b) This Fund shall be in the custody of the Treasurer of the Society
- "(c) The Fund shall be administered by the Relief Committee
- "(d) Payments from the Fund shall be made on the order of the Committee or in cases of especial urgency on order from the Chairman of the Committee.
- "(e) This Fund shall be maintained for the purpose of aiding members and the families of deceased members who are in need of assistance.
- "(f) The Relief Committee shall be the judges of all cases for relief
- "(g) Any member desiring relief shall have to apply to some member of the Relief Committee.
- "(h) Relief shall be in the form of a loan covered by a note, which bears no interest maturity set by the maker, or payable on demand. A note may be renewed

- "(i) A quorum of the Relief Committee, which is a majority, shall be necessary to transact business
- "(j) The Secretary of the Relief Committee shall keep an accurate record of all the transactions of the Committee and shall furnish reports at intervals as necessary and annually"

The President announced that the above Amendments will be voted upon at the next regular meeting of the Society

The following Resolutions were introduced

"Whereas, The Bronx County Medical Society having sustained a severe loss in the death of its honored associate, Seymour Basch, M D

"Resolved, That the Bronx County Medical Society record the sense of its loss in the death of Dr Basch and that a minute thereof be placed on the records of the Society, and be it

"Further Resolved, That a copy of these Resolutions be transmitted to the family of our departed member"

"Whereas, The Bronx County Medical Society having sustained a severe loss in the death of its honored associate, Jacob Wisansky, M D

"Resolved, That the Bronx County Medical Society record the sense of its loss in the death of Dr Wisansky and that a minute thereof be placed on the records of the Society, and be it

"Further Resolved, That a copy of these Resolutions be transmitted to the family of our departed member"

The above Resolutions were carried by a rising vote

The Scientific Program then proceeded as follows

1 The Treatment of Severe Diabetes with Complications, Alexander Goldman, M D

2 Problems in Metabolism for the Practitioner, George Baehr, M D

It was moved and carried that a vote of thanks be extended to the readers of the papers of the evening

I J LANDSMAN, M D,  
Secretary

A regular meeting of the Bronx County Medical Society, held at Montefiore Hospital, on June 15, 1927, was called to order at 9 P M, the President, Dr Friedman, in the Chair

The following new members were elected  
Emma L Bellows, Alfred Eichenberg, Nathan Benjamin Feinberg, Minna Feldblum, Martin F Hession, Harry S Pizer, Arpod Revay, William L Wintraub, Dominick F Zetena

The Secretary read the proposed amendments to the By-Laws of the Bronx County Medical Society as introduced at the May meeting Amend Section 11 (Standing Committees) by adding

"and a Relief Committee consisting of seven members—the President, Secretary and Treasurer of the Society and four other members"

Add—Section 82 (a)—

"Relief Fund and Relief Committee

"(a) The Society shall maintain a Relief Fund

"(b) This Fund shall be in the custody of the Treasurer of the Society

"(c) The Fund shall be administered by the Relief Committee

"(d) Payments from the Fund shall be made on the order of the Committee or in cases of especial urgency on order from the Chairman of the Committee

"(e) This Fund shall be maintained for the purpose of aiding members and the families of deceased members who are in need of assistance

"(f) The Relief Committee shall be the judges of all cases for relief

"(g) Any member desiring relief shall have

to apply to some member of the Relief Committee

"(h) Relief shall be in the form of a loan covered by a note, which bears no interest, maturity set by the maker, or payable on demand A note may be renewed

"(i) A quorum of the Relief Committee, which is a majority, shall be necessary to transact business

"(j) The Secretary of the Relief Committee shall keep an accurate record of all the transactions of the Committee and shall furnish reports at intervals as necessary and annually"

It was suggested that Paragraph (e) of Section 82 (a) be amended to read "This Fund shall be maintained for the purpose of aiding members, and also the families of deceased members who are in need of assistance." It was moved and carried that the proposed amendment to Section 11 and the addition of Section 82 (a) as amended be adopted, subject to the approval of the Council of the Medical Society of the State of New York

Dr Boas, Chairman of the Committee on Public Health and Medical Education, on request of the President, reported that the number of requests for the pamphlets advocating periodic health examinations has been comparatively few, and urged all the members to avail themselves of the opportunity to have these pamphlets sent directly to their patients or to them for distribution by applying to the Bronx Tuberculosis and Health Committee, 400 East Fordham Road, Bronx, New York City

The following resolutions were introduced

"Whereas, The Bronx County Medical Society having sustained a severe loss in the death of its honored associate, John J McGlade, M D,

"Resolved, That the Bronx County Medical Society record the sense of its loss in the death of Dr McGlade and that a minute thereof be placed on the records of the Society, and be it

"Further Resolved, That a copy of these resolutions be transmitted to the family of our departed member "

The above Resolutions were carried by a rising vote

The scientific program, which was principally clinical, then proceeded as follows

(1) Palliative Radiotherapy in Inoperative Cancer of the Breast, Maurice Lenz

(2) Some Cases of Nephritis, Sol Biloon

(3) Chronic Miliary Tuberculosis, Maurice Fishberg

(4) Two Cases of Severe Chronic Colitis, John L Kantor

(5) Pyelography in the Diagnosis of Extra-renal Tumors, Julius Gottesman

(6) Digitalis in the Treatment of Extra-systoles, Meyer M Harris

It was moved and carried that a vote of thanks be extended to Montefiore Hospital and to the gentlemen who presented the cases and reports

I J LANDSMAN, M D,  
Secretary

## COLUMBIA COUNTY MEDICAL SOCIETY

The semi-annual meeting of the Columbia County Medical Society was held at the Kinderhook Hotel, Kinderhook, N Y, Tuesday, May 10, 1927, the President, Dr J W Mambert, presiding

Members present Drs Bradley, Collins, Deane, Diefendorf, Galster, Garnsey, Mambert, Maxon, Noerling, C G Rossman, Skinner, Shank, Taylor, Tracy, Vedder, Wheeler, and Whitbeck Dr L Whittington Gorham, of Albany, was the guest of the society

The minutes of the last regular and special meetings were read and accepted as read

Dr Garnsey of the Comitia Minora presented the name of Dr Leon J Shank, of Kinderhook, for membership The application of Dr Shank was unanimously accepted

The secretary read considerable data pertaining to State Aid of County Public Health laboratories, that he was requested to get at the last special meeting, which was on motion received and placed on file

After a social dinner the society reconvened

and on motion of Dr Collins the committee appointed two years ago to make a survey of the advisability of a petition to the Board of Supervisors for a County Public Health laboratory, was instructed to confer with the trustees of the Hudson City Hospital, with the object of interesting them in the possibilities of the laboratory being located in the hospital and obtaining their aid in presenting the matter to the Board of Supervisors at their next annual meeting and to report progress at the annual meeting of the society

The scientific session was unusually interesting and instructive and several members suggested the idea that the society ought to meet every month Scarlet fever was the subject of an address by Dr Burke Diefendorf, and Pernicious Anemia by Dr L Whittington Gorham, of Albany Dr Gorham gave the society the benefit of the latest experiments in diet in the treatment of Pernicious Anemia and illustrated his address by lantern slides and microscopic demonstrations

CHARLES R SKINNER, M D, Secretary

## STEUBEN COUNTY MEDICAL SOCIETY

The summer meeting of the Steuben County Medical Society was held at the Gibson Hotel, Gibson Landing, on June 14th

A committee was appointed to consider the question of a county health department with instructions to report at the next meeting

The Scientific program was opened by Dr

N W Soble of Rochester with a paper on The Chronic Intestinal Invalid, which was illustrated by lantern slides

Dr W C Deen of Rochester presented an informal paper on the Graham test for disease of the gall bladder, which was illustrated by X-rays of cases

## WASHINGTON COUNTY MEDICAL SOCIETY

The semi-annual meeting of the Medical Society of the County of Washington was held at the Mary McClellan Hospital, Cambridge, May 24th, 1927, at 4 30 o'clock, with the President in the chair, and seventeen members present

Dr Paris presented the following resolution which was unanimously adopted

"Whereas The Mary McClellan Hospital is the only hospital in Washington County, and in all respects worthy of our support, be it

"Resolved, That we urge all members of this society and other physicians in this and adjacent counties to recommend the hospital to their patients, and do all in their power to protect its welfare

The President appointed Drs Tillotson, Park and Leonard a committee to select a chairman for the Washington County Cancer Research Committee

A bill for six dollars for flowers to Dr Heenan was ordered paid

Dr Fortune, Vice-President, presented eleven

cases of septicaemia All of the cases were subjected to a blood culture All of those showing a streptococci infection died and 85 per cent of those showing a staphylococci died Mercurochrome was used in some of the cases but with no definite results

Dr Leonard read a paper prepared by Dr H C Gordimer and Dr Thomas Ordway, on Epidemic Encephalitis, based upon a report of fifty cases

Dr Holmes read a paper on Polyneuritic Psychoses, noting that alcoholic cases did not recover, but the non-alcoholic made a fair recovery

Dr Pashley read a paper on crime and disease, noting that environment of the young developed tastes and desires for crime

Dr G S Pasquera gave a description of the X-ray findings in chest examinations, and emphasized the importance of history and clinical symptoms in arriving at a diagnosis

Dinner was served in the hospital Adjourned

S J BANKER, *Secretary*

---

## NASSAU COUNTY MEDICAL SOCIETY

A regular meeting of the Nassau County Medical Society was held at the Elk's Club, Freeport, on May 31st, with Dr William Runcie, President, in the chair

The Committee on Hospitalization reported that it is making a survey of the hospital conditions in the county, with a view of suggesting the location of new hospitals The committee was directed to have its report ready for the October meeting

The delegates to the State Society—Drs Van Kleck and Fensterer—reported that (1) the resolution on the lay-secretary was referred to the State Committee on By-laws

(2) The resolution on Post-Graduate work was introduced expressing thanks to the State Society for cooperation by the Committee on Post-graduate Education

(3) The report of the President of the Second District Branch stressed the importance of the lay-secretary

(4) Nassau County was among those whose dues were fully paid

The Committee on Social Functions reported that an outing meeting would be held on June 10, consisting of a shore dinner at the Seashore

It was moved by Dr Fensterer that two dollars per member be appropriated from the funds of the Society for the Flood Relief This will amount to \$290

It was voted that the bills for expenses of the delegates to the State Society be paid

Dr Russell L Cecil of New York gave a talk on "Pneumonia with Relation to the Present Status of Specific Therapy" A plea was made for the use of serum in Type 1 An interesting observation was made that Type 4 seemed to be modified by the use of Type 1 serum An immunity from one to two years was obtained after serum was used

The subject of "Fractures of the Skull, Some Clinical Observations" was presented by Dr Benjamin W Seaman of Hempstead The doctor said that a great majority of cases occurred as the result of impact from behind, causing frontal fracture The treatment consisted of elevation of the depression and spinal puncture for comparison with a subsequent puncture, and for the relief of pressure in the spinal canal

A D JAQUES,  
*Secretary*

## CLINTON COUNTY MEDICAL SOCIETY

The semi-annual meeting of the Clinton County Medical Society was made the occasion of a testimonial dinner to Dr W U Taylor of Mooers, and Dr W E Clough of Plattsburg, in recognition of the fact that Dr Taylor had celebrated his 75th birthday this year, and Dr Clough was nearly 70. Attendance, including guests, 33.

The business was for this occasion reduced to a minimum. A resolution was ordered prepared in honor of the memory of Dr M D Briggs, who died in the early part of this year, and who was, according to the original plans, to have been a third guest of honor at this meeting.

Directly after the business meeting a banquet was held at which Dr George Allen, President of the County Society, acted as toastmaster, and introduced Dr L G Barton of Plattsburg, President of the Fourth District Branch, who spoke on matters concerning the County, Branch, and State Societies, Major A S Bowen of Plattsburg Barracks who made a few congratulatory remarks, and was followed by Dr Joseph A Lawrence, State

Executive Secretary, in the same vein. Next was the speaker of the evening, Dr John B Wheeler, Professor of Surgery at the University of Vermont, who was an instructor at the time that Drs Taylor and Clough were students at this same university. His subject matter was mostly reminiscences of the good old times in the medical schools of fifty years ago, and proved intensely interesting. Among the topics touched were bleeding which was then going out of fashion and being superseded by leeches, the advent of antiseptics, and the objection at first of Dr Bigelow, the most prominent surgeon of New England at that time, to medical registration, and finally personal anecdotes about the teachers at the University of Vermont in the early eighties.

Dr Charles M Burdick, Superintendent of Dannemora State Hospital, presented the guests of honor with suitable tokens of friendship and esteem on behalf of the Medical Society, to which they responded, Dr Taylor adding to the fund of anecdotes supplied by Dr Wheeler, after which the meeting adjourned.

## QUEENS COUNTY MEDICAL SOCIETY

Following the custom in recent years the May meeting of the Medical Society of the County of Queens was deferred until June and was held as an outing meeting in affiliation with the Medical Association of the Greater City of New York. This year the combined outing was held at the Harbor Inn, Rockaway Park, on June 14th. It consisted of a shore dinner followed by a short Executive Session at which the following applicants, having been approved by the censors, were duly elected to membership.

*Active Members*

Frederick G Garttner, M D, 8135 88th Street, Glendale, L I

Anthony R Giambalvo, M D, 10143 Woodhaven Boulevard, Ozone Park

Seth Ransom Jagger, M D, 410 Amity Street, Flushing, L I

*Associate Member*

Frederick Weldin Splint M D, 292 Convent Avenue, New York City
